The Revised Standard Edition of
The Complete Psychological Works of

SIGMUND FREUD

Original translation by
James Strachey

Revised, supplemented and edited by
Mark Solms

VOLUMES I-XXIV

1886-1939

About the pagination of this eBook

This eBook contains a multi-volume set.

To navigate this eBook by page number, you will need to use the volume number and the page number, separated by a hyphen.

For example, to go to page 5 of volume 1, type “1-5” in the Go box at the bottom of the screen and click "Go."

To go to page 5 of volume 2, type “2-5”… and so forth.

*Sigmund Freud in 1884 (*aet. *28)*

This photograph was taken before Freud's trip to Paris. From there, he wrote to his fiancée Martha Bernays on February 2, 1886: 'There was a time that I was all ambition and eagerness to learn, when day after day I felt aggrieved that Nature in a benevolent mood hadn't stamped my face with that mark of genius which she occasionally bestows. Now for a long time I have known I am not a genius and cannot understand how I could ever have wished to be one.'

GENERAL PREFACE[1]

The Scope of the Standard Edition

The ground covered by this edition is shown by its title – *The Complete Psychological Works of Sigmund Freud*; but it is right that I should begin by indicating its contents more explicitly. My aim has been to include in it the whole of Freud's published psychological writings – that is, both the psychoanalytic and the pre-psychoanalytic. It does *not* include Freud's numerous publications on the physical sciences during the first fifteen years or so of his productive activity.[2] I have been fairly liberal in drawing the line here, for I have found a place for two or three works produced by Freud immediately after his return from Paris in 1886. These, dealing chiefly with hysteria, were written under the influence of Charcot, with scarcely a reference to mental processes; but they provide a real bridge between Freud's neurological and psychological writings. [xiii]

The *Standard Edition* does not include Freud's correspondence. This is of enormous extent and only relatively small selections from it have been published hitherto. Apart from 'Open Letters' and a few others printed with Freud's assent during his lifetime, my main exception to this general rule is in the case of his correspondence with Wilhelm Fliess during the early part of his career. This is of such vital importance to an understanding of Freud's views (and not only of his early ones) that much of it could not possibly be rejected. The first volume of the edition accordingly contains the 'Project' of 1895 and the series of 'Drafts' sent by Freud to Fliess between 1892 and 1897, as well as such portions of the letters themselves as are of definite scientific interest.

Nor, again, does the *Standard Edition* contain any reports or abstracts, published in contemporary periodicals, of the many lectures and papers given by Freud in early days at meetings of various medical societies in Vienna. The only exceptions here are the rare cases in which the report was made or revised by Freud himself.[3]

1 [This is James Strachey's preface to the original *Standard Edition*. Added comments by the Editor of this *Revised Standard Edition* are indicated by square brackets but discussion of the many ways in which the *RSE* differs from Strachey's *SE* (as described here) is deferred to the Preface to the Revised Edition (p. xxiii ff. below).]

2 Freud's own abstracts of the majority of these (they numbered some twenty-five in all, of varying length and importance) will be found in Volume 3 of the *RSE*, pp. 231–54. [Subsequent research has revealed that Freud published many more than twenty-five such works. They are all included in a companion edition to the *RSE*, *The Complete Neuroscientific Works of Sigmund Freud* (4 vols). See *RSE*, **24**, 143–276 for details.]

3 [An additional exception occurs in the *RSE*: a report of Freud's (1892*b*) lecture 'On Hypnosis and Suggestion' (p. 129 ff. below).]

On the other hand, the whole contents of the *Gesammelte Werke* (the only [xiv] approximately complete German edition) appear in the *Standard Edition*, besides a number of works which have either come to light since the completion of the *Gesammelte Werke*, or were, for various reasons, omitted by its editors. It has also seemed essential to include in Volume 2 Josef Breuer's share of the *Studien über Hysterie*, which was left out of both the German collected editions.[1]

The Plan of the Edition

The first problem for an editor faced by a total of some two million words was to decide how best to present them to his readers. Was the material to be arranged on a classificatory or a chronological basis? The first German collected edition (the *Gesammelte Schriften*, issued during Freud's life) attempted a division according to subject matter; the more recent *Gesammelte Werke* aimed at being strictly chronological. Neither plan was satisfactory. Freud's writings would not fit comfortably into categories, and strict chronology meant interrupting close sequences of his ideas. Here, therefore, a compromise was adopted. The arrangement is in the main chronological, but I have disregarded the rule in certain cases – where, for instance, Freud wrote an addendum many years after the original work (as with the *Autobiographical Study* in Volume 20) or where he himself grouped together a set of papers of various dates (as with the papers on technique in Volume 12). In general, however, each volume contains all the works belonging to a specified span of years. The contents of each volume (except of course where a single long work is concerned) are grouped in three classes: first I have placed the major work (or works) belonging to the period – which gives the volume its title; next come the more important writings on a smaller scale; and lastly come the really short (and usually relatively unimportant) productions. The chronology is so far as possible determined by the date of the actual *composition* of the work in question. Often, however, the only certain date is that of publication. Each item is consequently headed by the date of publication in round brackets, followed by the date of composition in square brackets, where this may reasonably be held to differ from the former. Thus the two last 'metapsychological' papers in Volume 14, though published in 1917, were almost certainly written at the same time as their three predecessors, in 1915. These last two are accordingly included in the same volume as the rest, and are headed '(1916–17 [1915])'. Incidentally, each volume contains its own bibliography and index, though a complete bibliography and an index to the whole series are planned for Volume 24.[2]

The German Sources

[xv] The translations in this edition are in general based on the last German editions published in Freud's lifetime. One of my main difficulties, however, has been the unsatisfactory nature of the German texts. The original publications, brought out

1 [All the deficiencies in the *GW* noted here have since been ameliorated. Conversely, several works now appear in the *GW Nachtragsband* that are not included in the *RSE*, namely Freud, 1908*g*, 1960*b*–*e*, 1967*a*.]

2 [Volume 24 of the *SE* was published in 1974, after Strachey's death.]

under Freud's immediate supervision, are as a rule trustworthy; but, as time went on and responsibility was delegated to other hands, errors began to creep in. This even applies to the first collected edition, published in Vienna between the Wars and destroyed by the Nazis in 1938. The second collected edition, which was printed in England under the greatest difficulties during the Second War, is largely a photocopy of its predecessor, but naturally shows signs of the circumstances in which it was produced. This, however, remains the only obtainable German edition of Freud's works with any claim to completeness.[1]

From 1908 onwards, Freud preserved his manuscripts; but in the case of works published in his lifetime I have not consulted them except in a few cases of doubt. Where writings have been published posthumously the position is different, and, in a few instances, especially in the case of the 'Project' (as will be seen from the Editor's Introduction to that work), the translation has been made direct from a photostat of the manuscript.

A serious defect in the German editions is the absence of any attempts at dealing with the very numerous changes in the text made by Freud in successive editions of some of his books. This applies in particular to *The Interpretation of Dreams* and the *Three Essays on the Theory of Sexuality*, both of which were to a very considerable extent recast in their later editions. For a serious student of the development of Freud's ideas it is of great interest to have the stratification of his views laid bare. Here, accordingly, I have endeavoured to note, for the first time, the dates at which the various alterations were made and to give the earlier versions in footnotes.

The Commentaries

It will be gathered from what has just been said that from first to last I have framed this edition with the 'serious student' in mind. The result has inevitably been a large amount of commentary, by which many readers will be irritated. Here I am inclined to quote Dr Johnson:[2]

'It is impossible for an expositor not to write too little for some, and too much for [xvi] others. He can only judge what is necessary by his own experience; and how long so-ever he may deliberate, will at last explain many lines which the learned will think impossible to be mistaken, and omit many for which the ignorant will want his help. These are censures merely relative, and must be quietly endured.'

The commentaries in the *Standard Edition* are of various kinds. Firstly there are the purely textual notes to which I have referred just above. Next come elucidations of Freud's very numerous historical and local allusions and literary quotations. Freud was a striking example of a man equally at home in both of what have been called the 'two cultures'. He was not only an expert neuroanatomist and physiologist; he was also widely read in the Greek and Latin classics as well as in the literatures of his own language and in those of England, France, Italy and Spain.[3] Most of his

1 It is now sold by S. Fischer Verlag of Frankfurt, but is entirely unrevised. [Two supplementary volumes, the *Gesamtregister* and *Nachtragsband*, were subsequently published in 1968 and 1987 respectively.]

2 From his Preface to Shakespeare.

3 Many passages in his works give evidence of his interest in the visual arts; nor perhaps was his attitude to music quite so negative as he liked it to be believed.

allusions may have been immediately intelligible to his contemporaries in Vienna, but are quite beyond the range of a modern English-speaking reader. Often, however, especially in *The Interpretation of Dreams*, these allusions play an actual part in the line of argument; their explanation could not be neglected, though it has called for considerable, and sometimes unsuccessful, research.

Another class of annotations is constituted by the cross-references. These should be of special value to a student. Freud has often dealt with the same topic several times, and perhaps in different ways, at various widely separated dates. Cross-references between these occasions over the whole range of the edition should help to overcome the objection to the general chronological treatment of the material.[1] Lastly, and more rarely, there are notes explanatory of Freud's remarks. These, however, are usually only extended examples of the cross-references; more elaborate discussions of Freud's meaning are usually reserved to yet another category of comment.

For, quite apart from these running explanations in the footnotes, each separate work without exception is provided with an introductory note. This varies in length according to the importance of the work. It opens in every case with a bibliography
[xvii] of the German text and of all its English translations. (No notice is taken of translations into other languages; and no attempt has been made to give a complete list of reprints subsequent to Freud's death in 1939.) This is followed by an account of what is known of the date and circumstances of the composition and publication of the work. After this comes some indication of its topic and of its place in the main current of Freud's thought. It is here, of course, that differences will be found. In the case of a short work of slight interest, there will be only a sentence or two. In the case of a major work, there may be an introductory essay covering several pages.

All these various kinds of editorial intervention have been governed by a single principle. I have aimed, consistently I hope, at allowing Freud to be his own expositor. Where there are obscurities I have looked for explanations in Freud's own writings; where there seem to be contradictions I have been content with laying the fact before the reader and enabling him to form a judgement of his own. I have done my best to escape being didactic, and have avoided any claim to *ex cathedra* authority. But, if I have withheld my own opinions, especially on matters of theory, it will be found that I have equally withheld *all* later commentaries and elaborations and criticisms from any source whatever. So that, almost without exception, this edition contains no references at all to other writers, however distinguished – apart, of course, from those quoted by Freud himself. (The immense proliferation of psychoanalytic literature since his death would in any case have imposed this decision.) The student should thus be able to approach Freud's writings uninfluenced by extraneous opinions.

It is in the matter of commentaries that I am most aware of the deficiencies of this edition, many of them irremediable. The numerous misprints and minor slips may be corrected, I hope, in Volume 24; but the faults I have in mind cannot so easily be put right. They spring in the main from the unripeness of the material. This is exemplified by what I have already mentioned – the absence of any really trustworthy German edition. But in fact, when work was starting on this edition more than

1 Needless to say, these cross-references make no pretence at being exhaustive. They are only intended as occasional signposts to suggest to the student possible lines of further research.

fifteen years ago, the whole region was unexplored and unmapped. The publication of Ernest Jones's life of Freud had not even begun; the correspondence with Fliess and the very existence of the 'Project' were unsuspected by most people. It is true that I received assistance from many quarters,[1] especially from Ernest Jones, who kept me abreast of his discoveries as he made them. Nevertheless, the *Standard Edition* is a piece of pioneering work, with all the inevitable errors and blunders that [xviii] that involves. I myself became better educated in Freud's ideas as time went on, and it is likely that the later-published volumes give evidence of this.[2]

Two handicaps in particular may be mentioned. It was of course impossible to realize the ideal situation of keeping the whole edition set up in print but open to correction till the last volume was finished. But it followed that a whole number of fundamental decisions had to be made before the first volume was published. These decisions included both questions of format and of the choice of technical terms, and, once made, they had in general to be adhered to throughout the edition. And some of them, of course, were likely to be regretted later.[3] Another source of deficiency, which the charitable critic will bear in mind, is that the *Standard Edition* has been in many ways an amateur production. It has been the work of a few individuals usually engaged in other occupations, and it has been without the background of any established academic machine ready to provide either personnel or accommodation.

The Translations

In considering a revised translation of Freud, the primary aim was bound to be the rendering of his meaning with the greatest possible accuracy. But another, and perhaps more difficult, problem could not be evaded: the problem of style. The literary merits of Freud's writing cannot possibly be dismissed. Thomas Mann, for instance, spoke of the 'purely artistic' qualities of *Totem and Taboo* – 'in its structure and literary form a masterpiece related and allied to all the great examples of German essay writing'.[4] These merits could scarcely be expected to survive translation, but some effort had to be made in that direction. When the *Standard Edition* was first planned, it was considered that it would be an advantage if a single hand were responsible for shaping the whole text; and in fact a single hand has carried out the greater part of the work of translation, and even where a former version has been used as a basis it will be found that a large amount of remodelling has been imposed. This [xix]

1 This was not universally true. In 1954 I was refused free use of the *Minutes* of the Vienna Psychoanalytical Society. [Strachey wrote in the *SE* version of this footnote that he was refused 'free access'. This revised version of the footnote appears in the Addenda and Corrigenda of the *SE* (Volume 24), in response to a letter of protest by Ernst Federn pointing out that Strachey had been offered access. Strachey had declined the offer, apparently due to restrictions placed on the use of the material by Herman Nunberg.]

2 It may be worth recording the actual order of their appearance. 1953: 4, 5, 7. 1955: 10, 18, 13, 2, 17. 1957: 11, 14. 1958: 12. 1959: 9, 20. 1960: 8, 6. 1961: 19, 21. 1962: 3. 1963: 15, 16. 1964: 22, 23. 1966: 1.

3 To mention a very trivial example, I think that if I were starting on the *Standard Edition* today I should probably suppress the tiresome hyphen in the word 'psycho-analysis'. [This has been done in the present edition, and the policy of omitting hyphens has been extended to several other words. For instance, 'super-ego', 'to-day' and 'ego-cathexis'.]

4 Thomas Mann (1929, 3).

unfortunately has involved the discarding, in the interests of this preferred uniformity, of many earlier translations that were excellent in themselves. The imaginary model which I have always kept before me is of the writings of some English man of science of wide education born in the middle of the nineteenth century. And I should like, in an explanatory and no patriotic spirit, to emphasize the word 'English'.

If I turn now to the primary question of the correct rendering of Freud's *meaning*, I must come into conflict with what I have just said. For wherever Freud becomes difficult or obscure it is necessary to move closer to a literal translation at the cost of any stylistic elegance. For the same reason, too, it is necessary to swallow whole into the translation quite a number of technical terms, stereotyped phrases and neologisms which cannot with the best will in the world be regarded as 'English'. There is also the special difficulty, which arises, for instance, in *The Interpretation of Dreams*, *The Psychopathology of Everyday Life*, and the book on jokes, of the appearance of material involving untranslatable verbal points. Here the easy alternatives are denied us of making a cut or of substituting some equivalent English material. We must fall back on square brackets and footnotes, for we are bound by the fundamental rule: Freud, the whole of Freud, and nothing but Freud.

As regards technical vocabulary, I have in general adopted the terms suggested in *A New German–English Psycho-Analytical Vocabulary* by Alix Strachey (1943), which was itself based on the suggestions of a 'Glossary Committee' set up by Ernest Jones twenty years earlier. In only a few instances have I departed from these authorities. Some individual words which raise controversial points are discussed in a separate note below.[1]

I have tried so far as possible to keep to the general rule of invariably translating a German technical term by the same English one. Thus, '*Unlust*' is always translated 'unpleasure' and '*Schmerz*' is always translated 'pain'. It should be noticed, however, that this rule is liable to lead to misunderstandings. For instance, the fact that '*psychisch*' is usually translated 'psychical' and '*seelisch*' 'mental' may lead to the notion that these words have different meanings, whereas I believe they are synonymous. The rule of uniform translation has, however, been carried further and extended to phrases and indeed to whole passages. When, as so often happens, Freud puts forward the same argument or tells the same anecdote on more than one occasion (sometimes at long intervals) I have tried to follow him, and to use, if he does, identical words, or, if he varies them, to do the same. Some not uninteresting points are in this way preserved in the translation. [xx]

I ought to say explicitly here that all additions to the text, however small, and all additional footnotes are indicated by square brackets.

Acknowledgements

Recognition must be paid, before anything else, to the exceedingly generous support to the scheme in its primordial stages by the members of the American Psychoanalytic Association (of which I am now proud to count myself an honorary member), on the initiative, in particular, of Dr John Murray of Boston, with the support of Dr W. C. Menninger, at that time President of the Association. Every previous attempt

1 [In this edition the 'Notes on Some Technical Terms' have been transferred to Volume 24, where they are supplemented by an entirely new set of notes.]

to raise the necessary capital had failed, and the whole project would have been abandoned without the magnificent gesture from America in subscribing in advance for some five hundred sets of the proposed edition. The sum was subscribed as an act of pure and indeed unreasonable faith, at a time when no concrete evidence existed of any such thing as the *Standard Edition*, and the patient subscribers were obliged to wait for as much as four or five years before the first volumes were delivered to them.

From that time onward, American support has been unswerving and has reached me from many quarters. I have enjoyed constant consultations throughout the years with Dr K. R. Eissler, who has put all the resources of the Sigmund Freud Archives at my disposal, besides giving me the friendliest personal reinforcement. Through him, too, I have had the benefit of access to the valuable material in the Library of the New York State Psychiatric Institute. I have, of course, been constantly indebted to Dr Alexander Grinstein and his *Index of Psychoanalytic Writings*. Before leaving the help I have had from America, I must mention two men, from widely separated regions, each of whom gave their support long ago to the dream of a complete Freud in English, but neither of whom lived to see its fulfilment: Otto Fenichel and Ernst Kris.

If I come now nearer home, my principal support has of course been from the Institute of Psycho-Analysis and in particular from its Publications Committee which, under changing names, has backed me through thick and thin from the earliest times, and in spite of what must often have seemed the most exorbitant financial demands. It seems a distortion to mention individual names, but I must recall once more my voluminous and instructive correspondence with Ernest Jones. I have special grounds for gratitude to Dr Sylvia Payne who was for a long time [xxi] Chairman of the Publications Committee.

Turning to the actual germination of the *Standard Edition*, it goes without saying that my first acknowledgements must be to the collaborator and assistants whose names will be found on the title page of each volume: Miss Anna Freud, my wife and Dr Alan Tyson. Miss Freud, in particular, has been ungrudging in devoting her precious leisure hours to reading through the whole of the translation and providing invaluable criticisms. The name of Miss Angela Richards (now Mrs Angela Harris) also appears on the title page of the present volume. In recent years she has, indeed, been my principal assistant and has taken charge of much of the editorial side of my work. My gratitude is also due to Mrs Ralph Partridge, who has prepared most of the indexes to the individual volumes, and to Mrs Ambrose Price and Mrs D. H. O'Brien, who between them typed out the whole of the material in the edition.[1]

The difficulties in the preliminary preparations for the edition were exacerbated by the complications arising from Freud's completely unbusinesslike handling of the copyrights in his translations. These troubles, particularly in regard to the American copyrights, were only solved by the energetic intervention of Mr Ernst Freud over a period of several months. The English side of this question was handled by the Hogarth Press and especially by Mr Leonard Woolf. Mr Woolf, who has been publishing the English translations of Freud for some forty years, himself took an active share in the evolution of this edition. I feel that my special, and somewhat guilty,

1 [The indexes in the *RSE*, both to the individual volumes and the edition as a whole, have been revised and can no longer be fairly attributed to Mrs Partridge.]

thanks are due to the publishers and to the printers for their tolerance in meeting my requirements.

It is right for me to add that, though I have received and profited immeasurably from the advice of many helpers, yet the final decision upon every point whether of the translation or the commentary was bound ultimately to rest with me, and it is therefore upon me that the sole responsibility must rest for the errors which time will no doubt bring to light in plenty.

Finally, perhaps I may be allowed a more personal acknowledgement – of my debt to the companion who has shared my task as a translator for so long. It is nearly half a century now since we spent two years together in Vienna in analysis with Freud, and since, after only a few weeks of our analysis, he suddenly instructed us to make a translation of a paper he had recently written – '"Ein Kind wird geschlagen"' – a
[xxii] translation now imbedded here in Volume 17. In the present enterprise she has given me constant help by her impartiality both in approval and criticism, and she alone carried me through some periods of physical difficulty when it seemed absurd to imagine that the *Standard Edition* could ever be brought to completion.

JAMES STRACHEY
Marlow, 1966

PREFACE TO THE REVISED EDITION

James Strachey's monumental achievement in editing Freud's complete psychological works in a uniform English translation was widely acclaimed when the *Standard Edition* first appeared in 1953–66. But even then, some critical voices were heard (e.g. Brandt, 1961). By the early 1980s, the rumblings had increased to the level of outrage (e.g. Bettelheim, 1983). In response, the Institute of Psychoanalysis in London – the intellectual custodian of the *Standard Edition* and its co-publisher – called a symposium on the topic in 1989. Shortly thereafter they appointed a committee to formulate a practical plan.[1] The Institute also called for papers on the topic to be submitted to the *International Review of Psycho-Analysis* and a special number was devoted to the controversy. The decision to produce a *Revised Standard Edition* was formally announced in the special number (Yorke, 1991).

That the project has come to fruition only now, three decades later, is due mainly to the fact that the planned revision gradually expanded as the project progressed. In the process, editorial responsibility passed from the late Albert Dickson to me (in 1995), and the very extensive editing of the *SE* that Dickson had undertaken on the basis of Strachey's marked-up copies and notes (and those of Angela Richards, the editor of the 24th volume, published in 1974) was incorporated into the present work.

The editorial policies that underpin this revised edition were not formulated by me alone. They were the collective responsibility of the committee just mentioned, and successive Boards of the Institute. The scholarly work, too, was not my sole responsibility; I relied heavily on the work of others. This applies above all to Ilse Grubrich-Simitis – who is James Strachey's true successor, and not only in Germany. Apart from allowing me to draw freely upon her many authoritative studies of Freud's writings, she also assisted me in almost every aspect of this edition, including formulation of some aspects of the editorial policy, although quite significant policy decisions were also made despite her better judgement. I have likewise relied heavily on Riccardo Steiner's research (especially his definitive series of publications on the history of the *Standard Edition*) and on his valuable personal support. The same applies to the painstaking bibliographical researches of the late Ingeborg Meyer-Palmedo and the late Gerhard Fichtner and (in more recent years) Albrecht Hirschmüller. The diverse ways in which these scholars have contributed to this edition far exceed the number of times their names are actually cited in it. The list of other colleagues to whom I owe similar scholarly

1 The names of the members of this committee deserve to be recorded: Pearl King (chair), Alex Pollock (treasurer), Joseph Sandler, Riccardo Steiner and Clifford Yorke.

debts, in varying degrees (starting with the names of K. R. Eissler and Patrick Mahony), is too long and ultimately too indeterminate to specify.

Nature and Scope of the Revision

The single most important principle upon which this revision is based is the decision to retain Strachey's *SE* translations – that is, to *revise* the translations rather than replace them. The justification for this decision is outlined in the Editor's Introduction to the 'Notes on the Translation of Some Technical Terms', now moved from Volume 1 to Volume 24. The reasoning behind the decision to retain Strachey's translations revolved mainly around questions of convention, but also the special problems of psychoanalytical terminology, and the limitations of translation itself.

Strachey mentioned in his General Preface above that he translated Freud as though he were an 'English man of science'. No blame can attach to the first part of this characterization, of Freud as an *English* man. When translating one must either use the conventions of the language being translated from or of that being translated into. Neither solution is better and it is impossible to employ them both; one simply has to make a choice. When translating the French equivalent of the *Standard Edition*, the *Oeuvres complètes*, Jean Laplanche opted for the former solution; James Strachey opted for the latter. In doing so, he made the choice that Freud himself always made when translating and when reviewing the translations of others (including translations of his own work). Having made this choice, certain implications followed naturally. Least important among these are the purely linguistic ones. It is, for example, simply bad English to render *Überich* as 'I over myself' or *Nachträglichkeit* as 'afterwardsness', as some commentators have seriously recommended. We should never forget the outstanding literary merits of Freud's writing, which are widely acknowledged; the masterly quality of his prose strains the abilities of any translator.

More pertinent are the conventions of English *scientific* writing and translation. This raises the spectre of the second part of Strachey's characterization, of Freud as a man of *science*. The most widely expressed criticism of Strachey's translation is that he 'falsely scientized' Freud; that he transformed his everyday descriptive language derived from ordinary German into an abstract technical language derived from ancient Greek and Latin. The first problem with this criticism is that Freud himself regularly described psychoanalysis as a natural science. It is therefore difficult to sustain the argument that it was Strachey who scientized Freud. Why, then, did Freud use everyday descriptive language? The answer is surely that, unlike English scientific writing, where it is common to use neologisms derived from classical antiquity, in German scientific writing it is conventional to use everyday descriptive words for the equivalent technical terms. This applies especially in anatomy, which is the science that Freud was most familiar with. It would therefore be entirely appropriate to translate the term *angelehnte Fasern* (which Freud coined in 1878 to describe a particular type of nerve fibre) as 'anaclitic' fibres; but it would be quite odd for an English anatomist to write about 'leaning-on' fibres, as is sometimes suggested for the psychoanalytic term *Anlehnung*. To translate like this would breach conventions of English scientific writing, while simultaneously obscuring the link between Freud's later, psychoanalytic and earlier, neuroscientific work.

It is of course true that there is also much that separates Freud's earlier and later work; psychoanalysis is not *only* natural science. This introduces the fact that Strachey was constrained not only by existing conventions in English scientific writing but also by those of the other intellectual traditions upon which Freud drew. The term *das Ich*, for example, Strachey's translation of which as 'the ego' was decried by many detractors, has a very long history in German philosophy. By the time that Strachey plumped for 'the ego', it was already well established as the standard English equivalent of *das Ich*. To break with that tradition would have been most peculiar, and again obscured important links. In light of this, it is not surprising that all of Strachey's predecessors in translating Freud used the same neologism.

This introduces the most important constraint upon Strachey: the existence of established conventions in English *psychoanalytic* translation. The ignoring of this tradition, so amply researched and documented by Riccardo Steiner, and so clearly acknowledged by Strachey himself, makes the widespread criticisms of his technical vocabulary not only unfair but also ill-informed. Almost all the technical terms for which Strachey has been condemned were, in fact, coined by others, some when he was still a schoolboy, long before the publication of the *Standard Edition*.

This tradition, including 'official' German–English vocabularies published by the Glossary Committee of the Institute of Psychoanalysis, culminated in the very idea of a *standard* edition. A standardized technical vocabulary necessarily has special meaning in a discipline like psychoanalysis, the object of study of which is – by definition – invisible. The very act of psychoanalysis is an act of translation. Freud was, as he wrote, therefore obliged to invent a 'figurative language' peculiar to depth psychology: 'We could not otherwise describe the processes in question at all, and indeed we could not have become aware of them' (Freud, 1920*g*; *RSE*, **18**, 57). Herein lies the tension between discovery and invention in psychoanalysis. Freud was in this sense his own first translator. And we, his psychoanalytic successors, translators all, are thereafter required to 'cathect' his figurative language with new observations. That is what a uniform psychoanalytical vocabulary is for: to ensure that we all know when we are talking about the same thing and when we are talking about different things; so that we can focus our attention on the *things* that we agree or disagree about, rather than the *words*. In a field where the things themselves are so hard to grasp, it is difficult to see what is to be gained by introducing a gaggle of synonymous words.

These are the reasons why we have chosen to retain – and revise – Strachey's translations. This does not imply that they are perfect translations; there are no such things. In the words of a famous English psychoanalyst, these are merely 'good enough' translations. But they are also the culmination of decades of effort, not only by Strachey but also by two whole generations of analysts, working closely with Freud himself to forge a generally agreed-upon English equivalent of the language he invented to describe a newly discovered but ultimately 'unknowable' part of nature. To abandon this vocabulary now would be foolhardy.

There is little sense in replacing Strachey's authoritative and stylistically excellent (though imperfect) translations with others which, at best, will be imperfect in new and different ways. The preferable approach must be to revise Strachey's translations, and supplement them with new editorial annotations aimed at compensating for the imperfections which are inherent in all translation.

The first and most important such annotations take the form of lengthy commentaries on the rendition of individual technical terms that have proved controversial. (These commentaries were compiled with the close assistance of Riccardo Steiner.) At the first appearance of such technical terms in each Freud text the original German word is given in square brackets and a superscript upper-case letter [T] indicates that the term is discussed in the 24th volume. Because the terms in the text are sometimes derivatives of the technical terms as they appear in Volume 24, the root word is given in the margin.[1] There (in *RSE*, **24**, 55–99) the commentaries appear, in alphabetical order, under the heading 'Notes on the Translation of Some Technical Terms'. The general plan of these commentaries is to acquaint the reader with the range of criticisms of Strachey's choices, the history behind those choices, the alternative English translations that have been proposed, and the arguments and counterarguments that have been mounted (not infrequently by Strachey himself). Little attempt is made in these commentaries to persuade the reader in one direction or another; the intention is mainly to inform. Although the commentaries focus on the published secondary literature, they also draw upon Strachey's unpublished notes and correspondences, mainly with Anna Freud and K. R. Eissler (both of whom wrote to him regularly about the *SE*), but also with Jones and Alix Strachey, and also upon an unpublished report by Ilse Grubrich-Simitis prepared specifically for this edition.[2]

A second set of annotations, which are similarly identified by superscript references in the text to the editorial notes in Volume 24, concern controversial translations of particular words or phrases as opposed to general technical terms occurring throughout Freud's writings. Instances of this type commonly concern titles of works and noteworthy sentences (e.g. 'where id was, there ego shall be') whose translation has attracted comment. These annotations are on the whole considerably shorter than those concerning the technical terms, and they are correspondingly limited in scope. Most of them simply record the published criticisms and the proposed alternatives. They are distinguished from the former category of annotations by the use in the Freud texts of a superscript lower-case [t] instead of the upper-case [T] used for the more general technical terms. This second set of annotations appears on pp. 105–33 of Volume 24, in chronological order, after the 'Notes on the Translation of Some Technical Terms', under the heading 'Annotations to Individual Translations'.

In a few places, usually where Strachey himself had done so, further commentaries (of both the above types) are provided in the editorial introductions and footnotes scattered throughout the twenty-three volumes. These are indexed in Volume 24 (pp. 601–6) under the heading 'Notes on Terms and their Uses'. Hopefully this mixture of methods strikes an adequate balance and informs the interested reader without detracting excessively from the original Freud texts.

The annotations discussed so far concern controversial translations as opposed to *erroneous* ones. In those few places where Strachey's translations are unequivocally

1 The words interpolated in square brackets are always Freud's own. German-speaking readers should note that no attempt has been made to 'adjust' them to conform with the English translation. In consequence, the German grammatical usage will sometimes appear incorrect to them.

2 This unpublished material is now housed in the Archives of the British Psychoanalytical Society, London.

incorrect (e.g. where he misread a word or omitted a clause), or where the typographer slipped, my approach has been simply to correct the error. Except in the cases that were recorded already in the 'Addenda and Corrigenda' in *SE*, **24**, I have identified all the significant instances of this type in additional editorial footnotes.

Needless to say, a sharp boundary between the controversial and the erroneous is not easily drawn. I have endeavoured to err on the side of caution, and treated as controversial some translations that others might consider frankly wrong. A particularly difficult borderline case was the translation of the German word '*Trieb*', which Strachey translated as 'instinct' but I have translated as 'drive' (as is now conventional in Anglo-American psychoanalysis). The reasoning behind my decision to treat Strachey's translation of *Trieb* as an error is spelt out in the relevant technical note (*RSE*, **24**, 85–8). The fact that this instance is both corrected in the text and discussed in the end notes recognizes that it is by no means an unequivocal error.

One further general change has been made in the revised translations: I have suppressed the use of hyphens, especially in such antiquated instances as 'psycho-analysis' and 'to-day'. Strachey would certainly have approved of this decision (see p. xix above). A list of the most common examples of this type is provided in the 'Note on the Revised Translation', which appears near the front of each volume (e.g. p. xxxiii below).

The fact that Strachey's translations have been retained in this revised edition does not mean that it includes no new translations. It has been necessary to include a surprisingly large amount of new Freud material. Fifty-six items not included in the *Standard Edition* appear in this revision, in their appropriate chronological positions (for a complete listing, see the 'List of New Freud Material', *RSE*, **24**, 19). Most of these items are very minor reviews, forewords, open letters and the like, but some of them are of considerable value. Foremost among these is the draft of one of Freud's famous missing metapsychological papers, 'Overview of the Transference Neuroses' (1985*a* [1915]), which now appears in Volume 14.[1]

Also of great interest – in no particular order – are the Four Documents in the Case of 'Nina R.' (1978*a* [1891–94]), the 'Mechanism of Obsessional Ideas and Phobias' (1895*h*), the 'Characteristics of My Own Dreams (Typical Dreams)' (1989*f* [after 1902]), the opening passages of 'Some Points of Agreement Between the Mental Lives of Savages and Neurotics', which formed the first essay in *Totem and Taboo* (1912*i*), the Review of Löwenfeld's *Psychical Compulsive Phenomena* (1904*f*), the Addendum to 'Psychical (or Mental) Treatment' (*c*. 1918/19), one of the Two Letters to Einstein (1994*a* [1929]), the Contributions to *Thomas Woodrow Wilson* [*c*. 1931–32], the Letter on Homosexuality (1951*a* [1935]) and a censored passage from Freud's 1927 postscript to *The Question of Lay Analysis* (1926*e*). In preparing the translations of this new material, I have endeavoured to retain stylistic and terminological consistency with Strachey's translations, as revised, even with regard to the tendency (denied in his preface above) to sometimes 'improve' on Freud's original texts.

Also consistent with the original *SE*, the *RSE* encompasses only Freud's complete psychological writings. It does not include his many pre-psychological works.

1 This is the only Freud text in the *RSE* that is edited and introduced by someone other than James Strachey or me. Ilse Grubrich-Simitis, who discovered the 'Overview of the Transference Neuroses' in 1983, was invited to do this work before I took over from Albert Dickson, which is when the Editor's role became more scholarly. However, it was unthinkable that I could improve on the editorial apparatus that Grubrich-Simitis had already provided for this extremely important text.

However, at the time of writing, I am some way towards completing the companion standard edition of *The Complete Neuroscientific Works of Sigmund Freud* (*NSW*, in four volumes), to complement the *RSE*. This will finally make available to the English-speaking world Freud's complete works. Or rather, his complete *published* works; for the scope of this edition, like the previous one, also does not extend to Freud's very voluminous correspondences and the like which were not published during his lifetime. As with the *SE*, only a few letters and unpublished manuscripts dealing with matters of particular importance found their way into this edition. Since the publication of the *SE*, however, many of Freud's most significant correspondences have become available in print, in good scholarly editions. These are listed in the revised 'Freud Bibliography' in Volume 24.

The 'Freud Bibliography' in this edition is, in fact, very heavily revised and expanded. It may seem absurd to note that Freud's list of publications has continued to grow, by hundreds of titles, through the decades since his death. But continue to grow it has – mainly due to the ongoing publication of his letters, but also because of occasional discoveries of previously unknown works, which in the case of Freud's pre-analytic publications resulted in the addition of more than three hundred newly discovered titles. This finally brings our official English bibliography of Freud's works into line with the hitherto far more authoritative German one (Meyer-Palmedo & Fichtner, 1999). The revised 'Freud Bibliography' also rectifies, on the basis of new findings, the chronological order of some of the items (resulting in physical relocations in this edition). In this regard, see the 'List of Relocated Freud Material in the Revised Edition' in Volume 24 (p. 23).

The lists of German editions and English translations that preceded Strachey's *SE* versions, mainly at the start of the Editor's Introductions and Notes, have also been updated for this edition. However, Strachey's policy of including only the major scholarly editions has been continued; mere reprintings are not systematically recorded.

The Editor's Introductions and Notes just mentioned (and the footnotes, too) have also been thoroughly updated, as have the editorial Appendixes. A great amount of Freud scholarship has accumulated in the decades since Strachey's death. In revising this important aspect of the editorial apparatus, I have leant especially heavily on Ilse Grubrich-Simitis's studies of the surviving Freud manuscripts (Grubrich-Simitis, 1993; trans., 1996) and on her other research and editorial work on Freud's writings. Her research has provided invaluable glimpses into the dynamics of Freud's actual process of writing. The process seems to have generally progressed through three stages: from rough *notes*, to manuscript *drafts*, to *fair copies* ready for the printers. Grubrich-Simitis's discovery of alternate, earlier versions of some important papers, such as *Beyond the Pleasure Principle* and *Moses and Monotheism*, has also been highly revealing. I have of course made abundant use of the work of other scholars, too, but I have assiduously resisted revisions based on supposition rather than fact. I have similarly tried not to burden the reader with my own opinions, although it was essential to opine on the merits of Strachey's translations, and I have also added some remarks on neuroscientific aspects of the 'Project for a Scientific Psychology' (1950*a* [1895]) and *The Interpretation of Dreams* (1900*a*). I decided to make more substantial editorial revisions in these two instances for particular reasons. In the case of the 'Project', I understood some neuroscientific

aspects of this iconic text (which is highly obscure in places) differently from my predecessor, who lacked specialist knowledge of the subject. In the case of *The Interpretation of Dreams*, substantial advances in neuroscientific knowledge which trench on the fundamental hypotheses of the book began to emerge almost immediately after the relevant volumes of the *SE* appeared in print. It seems likely that Strachey himself would have mentioned such paradigm-shifting developments had he been aware of them; I therefore make no apology for doing so, notwithstanding my personal involvement in the scientific developments at issue.

A particularly difficult policy decision concerned the question as to whether (and, if so, how) all these additions, revisions and corrections should be identified. They are subtle and pervasive. Repeatedly interrupting the editorial Introductions, Notes and footnotes to distinguish my contributions from Strachey's {by means of curly brackets or the like} would be excessively distracting for the reader and highly impracticable. This applies especially to the revised translations of the Freud texts, which have their own integrity; if the innumerable little changes I made on almost every page were footnoted, the notes would routinely occupy more than half the page. Therefore, my initial intention was only to describe the general policies I followed, and not to identify my interventions and contributions individually. I reasoned that readers who were interested in such matters could always compare the *SE* and *RSE* versions manually. Moreover, I was aware that hypertext functionality could be incorporated in the electronic edition of the *RSE*, which would enable readers to explore the differences between the two editions at the click of a button. After long deliberations, however, including the canvasing of opinion among representative samples of readers, the policy we have decided upon is to lightly underscore everything that distinguishes this revised edition from the previous one, in the print format too.

Everything here means everything other than the modernized spellings of words that recur extremely frequently (e.g. 'psycho-analysis'), the added marginalia (e.g. the German root words, which obviously did not appear in the *SE*), and purely technical changes like pagination in cross-references, fonts and point-sizes.[1] This editorial decision – which was not made lightly – has several disadvantages, such as the resultant repetitive underscoring of the word 'drive' and its cognates, and the highlighting of what many will consider trivial differences between the *SE* and *RSE*. However, distinguishing between the significant and the trivial is, unfortunately, both context-dependent and subjective. For example, in some places Strachey translated '*treibende Kraft*' as 'driving force' and in other places as 'motive force'. Since 'motives' have ideational content but 'drives' do not, my decision to change 'motive' to 'driving' is significant in some contexts but not in others. An assessment in each case is probably best left to the reader. The exact policy I have followed here is detailed in the 'Note on the Revised Translation', which appears at the front of each volume. The overriding intention behind this policy was to be as *transparent* as possible, which required an approach that is (1) simple and (2) consistently applied. I apologize in advance to readers for the distraction, and I reiterate that all the alternative policies that we considered had considerable drawbacks of their own. I have, however, asked the publishers to drop the underscoring in future printings of the

1 In the *RSE*, the editorial material has been set in smaller type than the Freud texts.

RSE, once it has become established as the canonical edition and interest recedes in the matter of how it differs from the old one.

Returning, now, to the distinction between supposition and fact, a case in point is that I have elected to retain references to the original (1950*a* [1887–1902]) edition of the Freud–Fliess letters, rather than update them with references to the subsequent (1985*c* [1887–1904]) unabridged version. Although the later version of Freud's side of this highly important correspondence is more complete, both the editorial apparatus and the translation are certainly not improvements on the earlier one (especially as revised by Strachey for the *SE*). Because Freud's previously unpublished letters to Fliess did not require inclusion in the *RSE*, and to avoid any implicit endorsement of Jeffrey Masson's tendentious editorial apparatus in the unabridged edition, I have continued to link the *RSE* references to the first edition. (It should be said that the German unabridged edition, prepared by Michael Schröter (see Freud, 1985*c*), exceeds the English one; Masson's editorial apparatus is toned down somewhat and Ernst Kris's valuable editorial apparatus is retained from the first edition (Freud, 1950*a*).)

Similar considerations led to an editorial decision to continue Strachey's policy of not revealing the identities of Freud's patients. At the risk of appearing priggish, it seemed important in an authorized edition of Freud's works to uphold the absolute ethical principle of confidentiality. To do otherwise would be to convey to present and future analysands that a limit to this principle is the degree of historical interest that might attach someday to their analyst, or to themselves. Psychoanalysis under such conditions becomes impossible. Therefore, although I have made use of the research findings of scholars who did publish the identities of Freud's patients, which cannot be undone, I have not reproduced their names here. I hope that this decision will be understood.

I hope that readers will understand also that no attempt has been made to improve the language Freud used to denote, for example, gay men and women as 'inverts', some non-European people as 'primitive' and 'savage', and the like. Although Freud was more enlightened than his contemporaries in particular respects, in others he was no less prejudiced than most bourgeois Europeans of his time, on matters such as race, class and gender. We acknowledge that both this language and its underlying belief systems are offensive, but the translator's task is to represent accurately what Freud wrote.

The last major difference between the *RSE* and the *SE* is the fact that the indexing has been thoroughly revised. This applies especially to the 'Index of Subjects' and 'Index of Names' in the 24th volume, and to the indexes in the individual volumes, which received much criticism over the years. Most of the more specialized indexes and listings in *SE*, **24**, which were sandwiched between the old Bibliography and Author Index and the original General Subject Index, now seem superfluous. These have either been deleted or incorporated into the new 'Index of Subjects'. Readers who wish to make use of the other *SE* indexes and listings can of course still readily do so. The 'Addenda and Corrigenda' in the old 24th volume, as already mentioned, have also been incorporated into the revised texts themselves. These changes made space in that volume for the lengthy annotations to the revised translations and the greatly expanded 'Freud Bibliography'. I have also expanded the 'Index of Editorial Annotations', which serves as a sort of super-index.

With all of these changes (including to the page format), it goes without saying that the pagination of the *RSE* does not match that of the *SE*. However, for ease of cross-referencing, not only to the original *SE* indexes but also – most importantly – to the vast secondary literature, the old pagination is recorded in square brackets in the margins of this edition.

From all of the above, it will be appreciated that the *RSE* is nothing more than its title implies: a *Revised* version of James Strachey's *Standard Edition*. I have accordingly applied Strachey's general editorial policies wherever possible; but it is important to acknowledge the limitations of this approach. No attempt has been made, for example, to systematically cross-reference the innumerable comments regarding his published works that Freud made in his vast correspondences. This revised edition aims only to update the existing *SE*, and it is accordingly an edition of equivalent scholarly level. It is not the ultimate historical-critical edition that Freud's work certainly deserves, and it makes no claims to being such (cf. Grubrich-Simitis, 1993, Part III; trans., 1996). Like the original *SE*, which Strachey described as 'an amateur production . . . the work of a few individuals usually engaged in other occupations', the *RSE* has been more a labour of love than a properly resourced academic (or even commercial) venture. I fear, as a result, that it may give rise to as many new questions as it has answered old ones. For this, despite the huge contributions made by the several scholars already mentioned, I, as the General Editor of this revision, must bear full responsibility.

Acknowledgements

It is unnecessary to reiterate the acknowledgement of my enormous debt to the scholars already mentioned, but I do want to repeat that the special few named at the outset are not the only ones to whom I am indebted. This applies particularly to the many bits of helpful information and advice that I received over the years, frequently unsolicited, from students of Freud, and especially from those engaged in tasks similar to my own – such as from the editors of the French and Dutch equivalents of this edition. With them I share the precious insight that Freud's genius reveals itself to the editor and translator in ways that cannot easily be appreciated by others.

The publishers of Freud's collected works in German – S. Fischer Verlag and Fischer Taschenbuch Verlag – have been most gracious in permitting us to use extensive editorial material from the *Gesammelte Werke Nachtragsband*, *Studienausgabe*, *Freud-Bibliographie* and other, individual paperback editions, as well as invaluable material from Ilse Grubrich-Simitis's *Zurück zu Freuds Texten*. This continues a valuable tradition of collaboration between Freud's authorized German and English publishers that has now extended over five decades.

In addition to my colleagues at the Institute of Psychoanalysis already mentioned, I must acknowledge the support (and sometimes the 'unreasonable faith') of successive Boards and Publications Committees of the Institute – and in particular of its General Managers during the period of my work, Nick Hall, Jon Levett and Caroline Langley. It must be said that some institutional actions were less reasonable than others, so I would particularly like to thank the Board which saw the project

through to its proper end under the Presidency of Rosine Perelberg. It was during her tenure that Rowman & Littlefield were selected to produce this high-quality edition, stewarded by the commendable Oliver Gadsby. Also richly deserving of acknowledgement is Elizabeth Coates Thummel, who chaired the ad hoc committee that brought this project to its happy conclusion. Henry Brown, an expert in copyright matters, now retired, also deserves special mention: he guided us through many tricky legal waters. (I have said that the main reason for the delay in completing this revision was the gradual expansion of the project, but that was not the only reason.) The final push to complete the project, when all else had failed, succeeded only because the Institute enlisted the support of a remarkably able copy editor, Mary Tobin. This acknowledgement is not merely conventional. Our debt to her is huge; and she is surely the best copy editor I have ever had the pleasure of working with. People not involved in this line of work cannot imagine the effort it entails. The Institute also engaged an indexing assistant, Natasha Jooste, and a supplementary copy editor with knowledge of the German language, Gyuri Fodor. Not least, but last as always, I must thank my assistants – both personal and research – especially the indomitable Paula Barkay and Eleni Pantelis, but also some others, once again too numerous and amorphously delimited to simply list.

MARK SOLMS
Franschhoek, 2024

NOTE ON THE REVISED TRANSLATION

The translations in this *Revised Standard Edition* are supplemented by four sets of notes:

(1) Lengthy commentaries on the English renditions of technical terms that are considered controversial are provided in Volume 24. Usually at the first appearance of each such technical term in each text, but sometimes in other places where the issue seems relevant, the original German word is interpolated in square brackets and a superscript upper-case [T] indicates that the term is discussed in the 24th volume. There (on pp. 55–99) the commentaries appear, in alphabetical order, under the heading 'Notes on the Translation of Some Technical Terms'. If the technical term appears in a derivate form in the text, the root word (as it appears in Volume 24) is provided in the margin. For example, if the interpolated word is the derivative [*überträgt*], the root technical term *Übertragung* appears in the margin.

(2) Shorter commentaries on the English rendition of specific words or phrases appearing in particular places (as opposed to general technical terms) that have attracted comment in the secondary literature are also provided in Volume 24. These minor commentaries are distinguished from those concerning general technical terms by the use of a superscript lower-case [t] in the place where the controversial translation appears. The corresponding set of annotations appears on pp. 105–33 of Volume 24, in chronological order, under the heading 'Annotations to Individual Translations'.

(3) Further interpolations in the translations of German words in square brackets are provided *ad hoc*, without superscript letters, for reasons that should be self-explanatory in each instance. For example, if a technical term which was referenced and discussed in a Note in Volume 24 appears again shortly afterwards in a way that illuminates the points discussed there, then it is silently referenced again. Some of these interpolations might seem odd to German-speaking readers, since no attempt is made to 'adjust' Freud's grammar to conform with the English translation (see the Preface to the Revised Edition, p. xxvi *n.* 1 above). The words in square brackets interpolated in the text are always exactly what Freud wrote.

(4) In a good few places, commentaries (of both types 1 and 2) are also provided in the Editors' introductory notes, appendices and footnotes to the text itself. These are indexed in Volume 24, on pp. 601–6, under the heading 'Notes on Terms and Their Uses'. Such commentaries are usually reserved for matters of translation that are likely to be of interest or value to the general reader, as opposed to those with a special interest in such technical matters.

The pagination of the original *Standard Edition* is provided also in the margins, in square brackets, to assist cross-referencing.

For the reasons explained in the 'Preface to the Revised Edition' (p. xxix above), all differences between the *SE* and *RSE* are identified through light underscoring of the text. This device was considered necessary to make readers aware of the subtle and pervasive revisions of the translations. The same applies to the revisions of the editorial apparatus. This underscoring will hopefully be removed in later editions of the *RSE*, once the revised edition has become established as the canonical one.

The overarching policy here has been to underscore all differences between the *SE* and *RSE*, with minimal exceptions, in order to ensure transparency. The three categories of exceptions (i.e. the differences that are *not* underscored) are (a) changes that are purely typographical and/or absolutely stereotyped across Volumes 1–23, (b) changes in the location of Freud texts within or between volumes, and (c) all the changes to Volume 24.

The rationale behind (a) is that we wanted to avoid any subjective judgements by the Editor of the *RSE* as to what is and what is not 'significant'. For example, some but not all readers might consider alterations to Strachey's spelling, grammar and punctuation to be trivial, but the potential significance – however subtle – varies with context. The rationale behind (b) is that these changes are indicated in the 'List of Relocated Freud Material in the Revised Edition', which is provided in Volume 24. These changes are also mentioned in the revised (and therefore underscored) editorial notes to the texts themselves. The rationale behind (c) is that the *RSE* version of Volume 24 is so utterly different from the *SE* version that readers can safely consider the volume as a whole to be new.

The following changes were deemed purely typographical and absolutely stereotyped, and are therefore exempted from underscoring:

(1) Changes in type-size, font and spacing (since they are objectively insignificant).

(2) The marginalia – including page numbers – and the superscript ^{T}s and ^{t}s (since they always represent changes).

(3) Changed page numbers in the cross-references and indexes (this follows logically from point 2).

(4) Altered footnote numbers (since new footnotes are always identified by the fact that the notes themselves are underscored, and the knock-on effects for numbering are objectively insignificant).

(5) Changes in running headings (since they repetitively echo changes that are underscored in the main body of text).

(6) Change from the singular possessive 'Editor's' to the plural 'Editors'' (since this applies throughout and follows logically from the fact that, unlike the *SE*, the *RSE* has two editors). In the few instances where the Editor is referred to in the singular, it is always clear from the context whether this means Strachey or Solms or, in the case of Freud (1985*a* [1915]), Grubrich-Simitis.

(7) This preliminary 'Note on the Revised Translation' (since it is obviously added; it applies only to the *RSE*).

(8) Captions to the illustrations (since they always represent changes).

(9) Changes in editorial style (since they are stereotyped and therefore need only be identified once, namely here):

- The word 'and' in two-author citations becomes '&', and a comma is inserted between author name/s and the publication date (e.g. Freud & Breuer, 1895*d*).
- Abbreviations of months (e.g. 'Oct.') and chapters ('Chap.') are spelt out ('October', 'Chapter').
- '*The*' is added to all editorial references to '*Interpretation of Dreams*'.
- Title abbreviations conform to modern usage (e.g. *G.W.* becomes *GW*).
- Punctuation is positioned inside closing quotation marks (e.g. 'The Latin word slipped your memory.').

(10) Modernized hyphenation of words is underscored, but not for those terms that occur very repetitively in the text (since they are stereotyped and the list is limited enough for readers to memorize). Here is the list, which implies also the plural and other grammatical forms of these terms:

anxiety-dream	*becomes*	anxiety dream
anxiety-hysteria	*becomes*	anxiety hysteria
day-dream	*becomes*	daydream
death-wish	*becomes*	death wish
dream-content	*becomes*	dream content
dream-interpretation	*becomes*	dream interpretation
dream-thought	*becomes*	dream thought
ego-cathexis	*becomes*	ego cathexis
ego-libido	*becomes*	ego libido
love-object	*becomes*	love object
object-cathexis	*becomes*	object cathexis
object-choice	*becomes*	object choice
object-libido	*becomes*	object libido
object-love	*becomes*	object love
object-presentation	*becomes*	object presentation
object-relation	*becomes*	object relation
psycho-analysis	*becomes*	psychoanalysis
sound-presentation	*becomes*	sound presentation
super-ego	*becomes*	superego
thing-presentation	*becomes*	thing presentation
to-day	*becomes*	today
wish-fulfilment	*becomes*	wish fulfilment
word-presentation	*becomes*	word presentation

REPORT ON MY STUDIES IN PARIS AND BERLIN

(1956 [1886])

EDITORS' NOTE

BERICHT ÜBER MEINE MIT UNIVERSITÄTS-JUBILÄUMS REISESTIPENDIUM UNTERNOMMENE STUDIENREISE NACH PARIS UND BERLIN

GERMAN EDITIONS

(1886 Date of composition.) [3]
1960 In J. & R. Gicklhorn's *Sigmund Freuds akademische Laufbahn im Lichte der Dokumente*, Vienna, 82.
1971 In S. Freud, *'Selbstdarstellung'; Schriften zur Geschichte der Psychoanalyse* (ed. I. Grubrich-Simitis), Frankfurt am Main, 129–38.
1987 *GW*, **Nachtr.**, 34–44.

ENGLISH TRANSLATIONS

'Report on my Studies in Paris and Berlin'
1956 *Int. J. Psycho-Anal.*, **37** (1), 2–7. (Tr. James Strachey.)
1966 *SE*, **1**, 5–15. (Slightly corrected reprint of the 1956 translation.)

The present translation is a lightly revised reprint of the *SE* version. It concerns the *Bericht* (report) only. The German editions include also, in various combinations, Freud's *Habilitationsgesuch*, *Curriculum vitae*, *Lehrplan* and *Reisestipendiums-gesuch*. These are included in *NSW*, **4**, where the present report is also reprinted.

The report with which the *Revised Standard Edition* of Freud's psychological works appropriately opens is a contemporary account by its protagonist of a historic event: the diversion of Freud's scientific interests from neurology to psychology.

The circumstances in which Freud obtained a travelling bursary from Vienna University in 1885 are related in detail by Ernest Jones (1953, 82–4). The grant, which was for 600 florins (worth at that time something under £50 or $250) and intended to cover a period of six months, was allotted by the College of Professors in the Faculty of Medicine; and to them he was expected to make a formal report on his return to Vienna. He spent about ten days in writing it almost immediately after his arrival back, and had finished it on April 22, 1886 (Jones, ibid., 252). On the initiative of Siegfried Bernfeld, this report was unearthed in the University Archives by Professor Josef Gicklhorn, and it became possible to publish it – in English first – seventy years after it was written, through the kindness of Dr K. R. Eissler, then Secretary of the

Sigmund Freud Archives in New York. The original, which remains in the Archives of the University of Vienna, consists of twelve manuscript sheets, of which the first contains only the title.

[4] The high importance which Freud himself always attributed to his studies under Charcot is a matter of common knowledge. This report marks his experience at the Salpêtrière with the utmost clarity as a turning point. When he arrived in Paris, his 'chosen concern' was with the anatomy of the nervous system; when he left, his mind was filled with the problems of hysteria and hypnotism. He was turning his back on neurology and was moving towards psychopathology. It would even be possible to assign a precise date to the change – in early December, 1885, when he ceased his work in the pathological laboratory of the Salpêtrière; but the inconvenient arrangements at that laboratory, which he himself puts forward as the explanation, were, of course, no more than a precipitating cause of the momentous shift in the direction of Freud's interests. Other and deeper factors were at work, and among them, no doubt, the great personal influence which Charcot evidently exercised on him. He expressed his sense of that influence most fully in the obituary which he wrote on his teacher's death a few years later (1893*f*), *NSW*, **4**.[1] Much, indeed, of what he says of Charcot in his present report found a place in his later study.

A more personal account of Freud's stay in Paris can be found in the series of lively letters written by him to his future wife (Freud & Bernays, 2011*b*, 2013*a*, 2015*a* and 2019*a* [1882–86]), some of which are included in English translation in the volume of his correspondence edited by Ernst Freud (1960*a*).

1 Though perhaps the most emotional expression of his feelings is to be found in his Preface to the translation of the *Tuesday Lectures* (pp. 163–4 below).

REPORT ON MY STUDIES IN PARIS AND BERLIN

Carried out with the assistance of a travelling bursary granted from the University Jubilee Fund (October, 1885 – end of March, 1886)

BY

DR SIGMUND FREUD

Dozent in Neuropathology at the University of Vienna

To the Most Honourable College of Professors in the Faculty of Medicine in Vienna

In my application for the award of the Travelling Bursary from the University Jubilee Fund for the year 1885–6, I expressed my intention of proceeding to the Hospice de la Salpêtrière in Paris and of there continuing my studies in neuropathology. Several factors had contributed to this choice. In the first place, there was the certainty of finding collected together in the Salpêtrière a large assemblage of clinical material such as exists in Vienna only dispersed in various departments and therefore not easily accessible. Then there was the great name of J.-M. Charcot,[1] who has now been working and teaching in his hospital for seventeen years. And lastly, I was bound to reflect that I could not expect to learn anything essentially new in a German University after having enjoyed direct and indirect instruction in Vienna from Professors T. Meynert and H. Nothnagel.[2] The French school of neuropathology,[3] on the other hand, seemed to me to promise something unfamiliar and characteristic in its mode of working, and moreover to have embarked on new fields of neuropathology, which have not been similarly approached by scientific workers in Germany and Austria. In consequence of the scarcity of any lively personal contact between French and German physicians, the findings of the French school – some of them (upon hypnotism) highly [5] [6]

1 [Jean-Martin Charcot (1825–93).]

2 [Theodor Meynert (1833–92) was Professor of Psychiatry in Vienna and Hermann Nothnagel (1841–1905) was Professor of Medicine.]

3 [This term covered a wider field in French and German usage than the equivalent English one.]

surprising and some of them (upon hysteria) of practical importance – had been met in our countries with more doubt than recognition and belief; and the French workers, and above all Charcot, were obliged to submit to the charge of lacking in critical faculty or at least of being inclined to study rare and strange material and to dramatize their working up of that material. Accordingly, when the honourable College of Professors distinguished me by the award of the Travelling Bursary, I gladly seized the opportunity which was thus offered of forming a judgement upon these facts based on my own experience, and I was happy, at the same time, to be in a position to realize the suggestion that had been made to me by my revered teacher, Professor von Brücke.[1]

While I was on a visit to Hamburg during the vacation, I was very kindly received by Dr Eisenlohr, well known as the representative of neuropathology in that city.[2] He enabled me to examine a considerable number of nerve patients in the General Hospital and the Heine Hospital[3] and also gave me access to the Mental Hospital of Klein-Friedrichsberg. But the studies with which I am concerned in the present report began only with my arrival in Paris in the first half of October, at the commencement of the academic year.

The Salpêtrière, which was the first place I visited, is an extensive set of buildings which, with its two-storey houses standing in quadrangles, as well as its courtyards and gardens, vividly recalls the General Hospital in Vienna. It has been put to many different uses during the course of years and its name (like that of our own '*Gewehrfabrik*') points to the first of these.[4] The buildings were finally converted into a home for aged
[7] women ('Hospice pour la vieillesse (femmes)' [1813]) and provide a refuge for five thousand persons. It followed from the nature of the conditions that chronic nervous diseases were bound to figure in this clinical material with particular frequency; and former '*médecins des hôpitaux*'[5] at

1 [Ernst Wilhelm von Brücke (1819–92) was Professor of Physiology, and Director of the Institute of Physiology, Vienna, in which Freud had worked from 1876 to 1882.]

2 [Freud spent six weeks during the autumn of 1885 at Wandsbek (just outside Hamburg), the home of his fiancée, Martha Bernays. – Dr C. Eisenlohr (1847–96) was Director of the Hamburg General Hospital. Freud speaks of him in his book on aphasia (1891*b*; *NSW*, **4**, Chapter I) as 'one of the most prudent German neurologists'.]

3 [The Jewish hospital.]

4 ['*Salpêtrière*' means a factory or store-house for saltpetre. It was built as an arsenal in the reign of Louis XIII in the early part of the seventeenth century. Similarly '*Gewehrfabrik*' means an ordnance factory. This had been the original use of the building which housed Brücke's Institute of Physiology in Vienna.]

5 ['*Médecin des hôpitaux*' corresponds roughly to a senior physician, and '*interne*' to a junior or house physician.]

the institution (Briquet,[1] for instance) had started on a scientific review of the patients. But the work could not be systematically pursued, on account of the custom among French *médecins des hôpitaux* of frequently changing the hospital in which they work and at the same time the special branch of medicine which they are studying, until their career carries them to the great clinical hospital of the Hôtel-Dieu. But J.-M. Charcot, when he was an '*interne*' at the Salpêtrière in 1856, perceived the necessity of making chronic nervous diseases the subject of constant and exclusive study, and he determined to return to the Salpêtrière as a *médecin des hôpitaux* and never thereafter to leave it. Charcot declares in his modesty that his only merit lies in his having carried out this plan. He was led by the favourable character of his material to the study of the chronic nervous diseases and their pathological anatomical basis; and for some twelve years he delivered clinical lectures as a voluntary worker without holding any official post,[2] till at last, in 1881, a Chair of Neuropathology was instituted at the Salpêtrière and assigned to him.

This appointment involved far-reaching changes in the conditions under which Charcot and his pupils (who had meanwhile become numerous) were working. An essential complement was added to the permanent material present in the Salpêtrière by opening a clinical section in which male as well as female patients were admitted for treatment and which was recruited from weekly consultations in an out-patient department ('*consultation externe*'). Further, there were placed at the disposal of the Professor of Neuropathology a laboratory for anatomical and physiological studies, a pathological museum, a studio for photography and the preparation of plaster casts, an ophthalmological room, and an electrical and hydropathic institute. These were situated in various portions of the great hospital and made it possible for the Director to secure the permanent cooperation of some [8] of his pupils, who were put in charge of these departments.[3]

The man who is at the head of all these resources and auxiliary services is now sixty years of age. He exhibits the liveliness, cheerfulness and formal perfection of speech which we are in the habit of attributing to the French national character; while at the same time he displays the patience and love of work which we usually claim for our own nation.

1 [Paul Briquet (1796–1881), author of a monumental treatise on hysteria (1859).]

2 [During this time he held the Chair of Pathological Anatomy at the Collège de France, but worked at the Salpêtrière on a voluntary basis.]

3 [The history of these changes and the extent of the reorganization of the Salpêtrière were described in detail by Charcot himself in the first of the lectures translated by Freud in 1886 (see footnote, p. 19 below). Freud's account is largely based on this.]

The attraction of such a personality soon led me to restrict my visits to one single hospital and to seek instruction from one single man. I abandoned my occasional attempts at attending other lectures after I had become convinced that all they had to offer were for the most part well-constructed rhetorical performances. The only exceptions were Professor Brouardel's forensic autopsies and lectures at the Morgue, which I rarely missed.[1]

My work in the Salpêtrière itself took on a different shape from what I had originally laid down for myself. I had arrived with the intention of making one single question the subject of a thorough investigation; and since in Vienna my chosen concern had been with anatomical problems, I had selected the study of the secondary atrophies and degenerations that follow on affections of the brain in children. Some extremely valuable pathological material was put at my disposal; but I found that the conditions for making use of it were most unfavourable. The laboratory was not at all adapted to the reception of an extraneous worker, and such space and resources as existed were made inaccessible owing to lack of any kind of organization. I thus found myself obliged to give up anatomical work[2] and rest content with a discovery concerned with the relations of the nuclei of the posterior column in the medulla oblongata. Later, however, I had an opportunity of resuming some similar investigations with Dr von Darkschewitsch (of Moscow); and our collaboration led to
[9] a publication in the *Neurologisches Centralblatt* (1886, **5**, 121), bearing the title 'Über die Beziehung des Strickkörpers zum Hinterstrang und Hinterstrangskern nebst Bemerkungen über zwei Felder der Oblongata'.[3]

In contrast to the inadequacy of the laboratory, the clinic at the Salpêtrière provided such a plethora of new and interesting material that it needed all my efforts to profit by the instruction which this favourable opportunity afforded. The weekly timetable was divided as follows. On Mondays Charcot delivered his public lecture, which delighted its hearers by the perfection of its form, while its subject matter was familiar from the work of the preceding week. What these lectures offered was

1 [P. C. H. Brouardel (1837–1906) was a name famous in medical jurisprudence. Freud wrote appreciatively of him in a Preface which he contributed nearly thirty years later (1913*k*) to a German translation of Bourke's *Scatalogic Rites of all Nations*. He quoted there one of Brouardel's sayings which had struck him: 'Les genoux sales sont le signe d'une fille honnête.' ('Dirty knees are the sign of a respectable girl.')]

2 [This was at the beginning of December, 1885 (Jones, 1953, 231).]

3 ['On the relation of the restiform body to the posterior column and its nucleus with some remarks on two fields of the oblongata' (Freud, 1886*b*), *NSW*, **1**. The paper is dated 'Paris, January 23, 1886'. For a brief account of its contents and of Freud's relationship with L. O. von Darkschewitsch (1858–1925), see Jones, 1953, 205 and 225–6. See also Freud's own abstract of the paper (1897*b*), *RSE*, **3**, 237.]

not so much elementary instruction in neuropathology as information, rather, on the Professor's latest researches; and they produced their effect primarily by their constant references to the patients who were being demonstrated. On Tuesdays Charcot held his '*consultation externe*', at which his assistants brought before him for examination the typical or puzzling cases among the very large number attending the out-patient department. It was sometimes discouraging when the great man allowed some of these cases, to use his own expression, to sink back 'into the chaos of a still unrevealed nosography'; but others gave him the opportunity of using them as a peg for the most instructive remarks on the greatest variety of topics in neuropathology.[1] Wednesdays were partly devoted to ophthalmological examinations, which Dr Parinaud[2] carried out in Charcot's presence. On the remaining days of the week Charcot made his rounds of the wards, or continued whatever researches he was engaged in at the time, examining patients for this purpose in his consulting room.

In this way I had an opportunity of seeing a long series of patients, of examining them myself and of hearing Charcot's opinion on them. But what seems to me to have been of greater value than this positive gain in experience was the stimulus which I received during the five months I spent in Paris from my constant scientific and personal contact with [10]
Professor Charcot.

As regards scientific contact I was scarcely given preference over any other foreigner. For the clinic was accessible to any physician who presented himself; and the Professor's work proceeded openly, surrounded by all the young men acting as his assistants as well as by the foreign physicians. He seemed, as it were, to be working with us, to be thinking aloud and to be expecting to have objections raised by his pupils. Anyone who ventured might put in a word in the discussion and no comment was left unnoticed by the great man. The informality of the prevailing terms of intercourse, and the way in which everyone was treated on a polite footing of equality – which came as a surprise to foreign visitors – made it easy even for the most timid to take the liveliest share in Charcot's examinations. One could see how, to begin with, he would stand undecided in the face of some new manifestation which was hard to interpret, one could follow the paths along which he endeavoured to arrive at an understanding of it, one could study the way in which he

1 [These discussions formed the material of Charcot's famous series of volumes, *Leçons du mardi* (*Tuesday Lectures*), one of which (for the year 1887–8) was later translated into German by Freud himself (1892–94*a*) (see p. 161 below and *NSW*, **4**).]

2 [Henri Parinaud (1844–1905), a well-known eye specialist.]

took stock of difficulties and overcame them, and one could observe with surprise that he never grew tired of looking at the same phenomenon, till his repeated and unbiased efforts allowed him to reach a correct view of its meaning.[1] When, in addition to all this, the complete sincerity is borne in mind which the Professor displayed during these sessions, it will be understood how it is that the writer of this report, like every other foreigner in a similar position, left the Salpêtrière as Charcot's unqualified admirer.

Charcot used to say that, broadly speaking, the work of anatomy was finished and that the theory of the organic diseases of the nervous system might be said to be complete: what had next to be dealt with was the neuroses. This pronouncement may, no doubt, be regarded as no more than an expression of the turn which his own activities have taken. For many years now his work has been centred almost entirely on the neuroses, and above all on hysteria, which, since the opening of the out-patient department and of the clinic, he has had an opportunity of studying in men as well as women.

I will venture to sum up in a few words what Charcot has achieved in the clinical study of hysteria. Up to now, hysteria can scarcely be regarded as a name with any well-defined meaning. The state of illness to
[11] which it is applied is only characterized scientifically by *negative* signs; it has been studied little and unwillingly; and it labours under the odium of some very widespread prejudices. Among these are the supposed dependence of hysterical illness upon genital irritation, the view that no definite symptomatology can be assigned to hysteria simply because *any* combination of symptoms can occur in it, and finally the exaggerated importance that has been attributed to simulation in the clinical picture of hysteria. During the last few decades a hysterical woman would have been almost as certain to be treated as a malingerer as in earlier centuries she would have been certain to be judged and condemned as a witch or as possessed of the devil. In another respect there has, if anything, been a step backward in the knowledge of hysteria. The Middle Ages had a precise acquaintance with the 'stigmata' of hysteria,[2] its somatic signs, and interpreted and made use of them in their own fashion. In the out-patient department in Berlin, however, I found that these somatic signs of hysteria were as good as unknown and that in general, when a

1 [This was based on Charcot's own words, often quoted by Freud. See the obituary (1893*f*), *NSW*, **4**; *RSE*, **3**, 12 *n*. 2.]

2 [Cf. 'The Aetiology of Hysteria' (1896*c*), ibid., **3**, 200 *n*. 2.]

diagnosis of 'hysteria' had been made, all inclination to take any further notice of the patient seemed to be suppressed.

In his study of hysteria Charcot started out from the most fully developed cases, which he regarded as the perfect types of the disease.[1] He began by reducing the connection of the neurosis with the genital system to its correct proportions by demonstrating the unsuspected frequency of cases of male hysteria and especially of traumatic hysteria. In these typical cases he next found a number of somatic signs (such as the character of the attack, anaesthesia, disturbances of vision, hysterogenic points, etc.), which enabled him to establish the diagnosis of hysteria with certainty on the basis of positive indications. By making a scientific study of hypnotism – a region of neuropathology which had to be wrung on the one side from scepticism and on the other from fraud – he himself arrived at a kind of theory of hysterical symptomatology. These symptoms he had the courage to recognize as for the most part real, without neglecting the caution demanded by the patients' disingenuousness. Rapidly increasing experience with the most excellent material soon enabled him to take into account as well the deviations from the typical picture. At the time when I was obliged to leave the clinic, he was passing on from the study of hysterical paralyses and arthralgias to that of hysterical atrophies, of whose existence he was able to convince himself only during the last few days of my visit. [12]

The enormous practical importance of male hysteria (which is usually unrecognized) and particularly of the hysteria which follows upon trauma was illustrated by him from the case of a patient who for nearly three months formed the centre point of all Charcot's studies. Thus, by his efforts, hysteria was lifted out of the chaos of the neuroses, was differentiated from other conditions with a similar appearance, and was provided with a symptomatology which, though sufficiently multifarious, nevertheless makes it impossible any longer to doubt the rule of law and order. I had a lively interchange of opinions with Professor Charcot (both by word of mouth and in writing) on the points of view arising from his investigations. This led to my preparing a paper which is

1 [Charcot's use of the 'type' as a starting point for forming a clinical picture of an illness was explained at some length by Freud in his Preface to the *Leçons du mardi* (see p. 162 f. below) and, more briefly, in his Charcot obituary (1893*f*), *NSW*, **4**; *RSE*, **3**, 12.]

to appear in the *Archives de Neurologie* and is entitled 'Vergleichung der hysterischen mit der organischen Symptomatologie'.[1]

I must remark here that the proposal to regard neuroses arising from trauma ('railway spine'[2]) as hysteria has met with lively opposition from German authorities, especially from Dr Thomsen and Dr Oppenheim, assistant physicians at the Charité[3] in Berlin. I made the acquaintance of both these gentlemen later in Berlin and hoped to seize the opportunity of ascertaining whether this opposition was justified. But unluckily the patients concerned were no longer at the Charité. I formed the opinion, however, that the question is not ripe for decision, but that Charcot had rightly begun by considering the typical and simpler cases, whereas his German opponents had started on the study of the indeterminate and more complicated examples. The assertion that such severe forms of
[13] hysteria as those on which Charcot based his work did not occur in Germany was disputed in Paris; attention was drawn to the historical accounts of similar epidemics, and the identity of hysteria at every time and place was insisted upon.

Nor did I neglect the opportunity of acquiring a personal acquaintance with the phenomena of hypnotism, which are so astonishing and to which so little credence is attached, and in particular with the '*grand hypnotisme*' ['major hypnotism'] described by Charcot. I found to my astonishment that here were occurrences plain before one's eyes, which it was quite impossible to doubt, but which were nevertheless strange enough not to be believed unless they were experienced at first hand. I saw no sign, however, that Charcot showed any special preference for rare and strange material or that he tried to exploit it for mystical purposes. On the contrary, he regarded hypnotism as a field of phenomena which he submitted to scientific description, just as he had done many years before with multiple sclerosis or progressive muscular atrophy. He did not seem to me to be at all one of those men who marvel at what is rare rather than what is usual; and the whole trend of his mind

1 ['A Comparison between Hysterical and Organic Symptomatology.' The paper was only published seven years later and with a different title: 'Quelques considérations pour une étude comparative des paralysies motrices organiques et hystériques' ('Some Points for a Comparative Study of Organic and Hysterical Motor Paralyses') (1893*c*, p. 187 below; *NSW*, **4**). It appeared in French in the *Archives de Neurologie* in July, 1893, just before Charcot's death. For an account of the circumstances, see the Editors' Note on pp. 185–6 below.]

2 [In English in the original. The term (and similarly 'railway brain') had been introduced by Sir John Erichsen (1818–96).]

3 [The great teaching hospital attached to the University of Berlin. Robert Thomsen (1858–1914) and Hermann Oppenheim (1858–1919) were assistants of C. F. O. Westphal (1833–90), Professor of Nervous and Mental Diseases. Oppenheim, later Professor of Neurology in Berlin, became one of the most vehement opponents of psychoanalysis.]

leads me to suppose that he can find no rest till he has correctly described and classified some phenomenon with which he is concerned, but that he can sleep quite soundly without having arrived at the physiological explanation of that phenomenon.

I have given considerable space in this report to remarks on hysteria and hypnotism because I had to deal with what was completely novel and the subject of Charcot's own particular studies. If I have said less on the organic diseases of the nervous system, I should not like it to be supposed that I saw little or nothing of them. I will mention only some of the specially interesting cases among the wealth of notable material presented. Such, for instance, were the forms of hereditary muscular atrophy recently described by Dr Marie;[1] though these are no longer to be counted among diseases of the nervous system, they are still under the care of neuropathologists. Again, I may mention cases of Ménière's disease, of multiple sclerosis, of tabes, with all its complications and particularly accompanied by the disease of the joints described by Charcot, of partial epilepsy, and of other forms of illness that go to make up the stock material of clinics and out-patient departments for nervous diseases. Among functional illnesses (apart from hysteria), chorea and the various forms [14] of 'tic' (e.g. Gilles de la Tourette's disease) were receiving special attention during the time of my attendance.

When I heard that Charcot was intending to bring out a fresh collection of his lectures, I offered to make a German translation of it; and thanks to this undertaking I came into closer personal contact with Professor Charcot and was also able to prolong my stay in Paris beyond the period covered by my Travelling Bursary. This translation is to be published in Vienna in May of this year by the firm of Toeplitz and Deuticke.[2]

Finally, I must mention that Professor Ranvier[3] of the Collège de France was kind enough to show me his excellent preparations of nerve cells and neuroglia.

1 [Pierre Marie (1853–1940) became editor of the Paris *Revue neurologique*, to which Freud later contributed some papers in French. He succeeded Charcot at the Salpêtrière.]

2 [The book's publication seems to have been delayed for some months; it appeared under the title *Neue Vorlesungen über die Krankheiten des Nervensystems insbesondere über Hysterie* (*New Lectures on the Diseases of the Nervous System, particularly on Hysteria*). Freud's Preface was dated July 18, 1886. For fuller information, see p. 17 below, where Freud's Preface is translated. For Freud's footnotes, see *NSW*, **4**.]

3 [Louis-Antoine Ranvier (1835–1922), the famous histologist, frequently cited by Freud in his earliest scientific publications. See *NSW*, **1**.]

My stay in Berlin, which lasted from the first of March to the end of that month, fell during the vacation period. Nevertheless I had ample opportunities for examining children suffering from nervous diseases in the out-patient clinics of Professors Mendel and Eulenburg and of Dr A. Baginsky, and I was everywhere most politely received.[1] Repeated visits to Professor Munk and to Professor Zuntz's[2] agricultural laboratory (where I met Dr Loeb of Strassburg[3]) enabled me to form my own judgement on the controversy between Goltz and Munk on the question of the localization of the visual sense in the cortex of the brain.[4]
[15] Dr B. Baginsky, of the Munk laboratory, was kind enough to demonstrate to me his preparations of the course of the acoustic nerve and to ask my opinion of them.[5]

I regard it as my duty to offer my warmest thanks to the College of Professors in the Faculty of Medicine in Vienna for selecting me for the award of the Travelling Bursary. In doing so, the College (among whom are numbered all my much respected teachers) have given me the possibility of acquiring valuable knowledge, of which I hope to make use as Dozent[6] in nervous diseases as well as in my medical practice.

Vienna, Easter, 1886

1 [Emanuel Mendel, Professor of Psychiatry, edited the *Neurologisches Centralblatt*, to which Freud made many contributions and for which he undertook to abstract neurological literature published in Vienna. – Albert Eulenburg (1840–1917) was Professor of Neurology and Electrotherapy. – Adolf Baginsky (1843–1918) was author of an important textbook on paediatrics and editor of the *Zentralblatt für Kinderheilkunde*, for which Freud also undertook to abstract the neurological literature. – For Freud's abstracts, see *NSW*, **1**.]

2 [Nathan Zuntz (1847–1920), from 1880 Professor of Physiology at the Agricultural College, Berlin.]

3 [This was no doubt Jacques Loeb (1859–1924), the celebrated biologist, who took his medical degree at Strassburg in 1885.]

4 [Friedrich Goltz (1834–1902) and Hermann Munk (1839–1912) had a long and acrimonious controversy on this subject. Freud's interest in the general question of the localization of function was shown soon afterwards in his book on aphasia (1891*b*), *NSW*, **4**.]

5 [Benno Baginsky (1848–1919) was assistant to Professor Hermann Munk in the physiological laboratory of the Berlin Veterinary College. Freud himself was concerned with the origin of the acoustic nerve (Freud, 1886*c*), *NSW*, **1**.]

6 [Freud had been appointed a 'Privatdozent' (roughly equivalent to a university lectureship) at about the same time as he had been granted the travelling bursary (see Jones, 1953, 76 ff.).]

PREFACE TO THE TRANSLATION OF CHARCOT'S *LECTURES ON THE DISEASES OF THE NERVOUS SYSTEM* (1886)

EDITORS' NOTE

PREFACE TO THE TRANSLATION OF CHARCOT'S *LEÇONS SUR LES MALADIES DU SYSTÈME NERVEUX: TOME TROISIÈME*

GERMAN EDITIONS

1886 In J.-M. Charcot, *Neue Vorlesungen über die Krankheiten des Nervensystems insbesondere über Hysterie* ['New Lectures on the Diseases of the Nervous System, particularly on Hysteria'], Leipzig and Vienna: Toeplitz and Deuticke, iii–iv. [19]

1987 *GW*, **Nachtr.**, 52–3. (Preface only.)

2015 *SFG*, **2**, 77–80. (Preface only.)

ENGLISH TRANSLATION

1966 *SE*, **1**, 21–2. (Preface only.) (Tr. James Strachey.)

The present translation is a lightly revised reprint of the *SE* version. Freud's translation of two of the lectures (XXIII and XXIV) was published in advance in the *Wien. med. Wschr.*, **36** (20), 711–15, and (21), 756–9 (May 15 and 22, 1886), under the title 'Über einen Fall von hysterischer Coxalgie aus traumatischer Ursache bei einem Manne' ('On a case of hysterical coxalgia in a man, with traumatic origin') (Freud, 1886*e*). The publication of the book itself cannot have been earlier than July, 1886 (the date of Freud's Preface); but it took place in any case before the French original (Paris, 1887), as Freud mentions in his Preface.

A more detailed account of how Charcot gave Freud the commission to make the German translation of this book was given in his *Autobiographical Study* (1925*d*), *RSE*, **20**, 10, and also in a contemporary letter of Freud's to his future wife (December 12, 1885), printed in English translation in Freud, 1960*a* (Letter 88).

For Freud's half-dozen footnotes, see *NSW*, **4** (where this Preface is also reprinted). As Freud himself indicates in the Preface, his footnotes merely record later developments in one or two of the case histories reported in the text and in one instance a recent change of opinion by Charcot on a minor point of diagnosis. Three of the lectures (XI, XII and XIII) deal with aphasia. A short comment by Freud shows that he was already specially interested in the subject, on which he was to write his

[20] monograph five years later. He gave a short account there of Charcot's views (1891*b*; *NSW*, **4**), and referred back to the present work.

Jones (1953, 230) tells us that Charcot rewarded Freud for the translation by the gift of a complete set of his works bound in leather, with the inscription: 'À Monsieur le Docteur Freud, excellents souvenirs de la Salpêtrière. Charcot.'

PREFACE TO THE TRANSLATION OF CHARCOT'S *LECTURES ON THE DISEASES OF THE NERVOUS SYSTEM*

An undertaking such as the present one, which aims at introducing the teachings of a master of clinical medicine to wider medical circles, surely calls for no justification. I propose, therefore, to say only a few words on the origin of this translation and on the contents of the lectures contained in it. [21]

When in the winter of 1885 I arrived at the Salpêtrière for a stay of almost half a year, I found that Professor Charcot (then working in his sixties with all the freshness of youth) had turned away from the study of the nervous diseases that are based on organic changes and was devoting himself exclusively to research into the neuroses – and particularly hysteria. This change was related to the alterations (described in the opening lecture in this volume) which had taken place in the conditions of Charcot's work and teaching in 1882.[1]

After I had overcome my initial bewilderment at the findings of Charcot's new investigations, and after I had learnt to appreciate their great importance, I asked Professor Charcot's permission to make a German translation of the lectures in which these new theories are contained. And here I have to thank him not only for the readiness with which he gave me his permission, but also for his further assistance, which made it possible for the German edition actually to be published several months *before* the French one. By the author's instructions I have added a small number of notes – mostly addenda to the histories of the patients dealt with in the text.

The core of this book lies in the masterly and fundamental lectures on hysteria, which, along with their author, we may expect to open a new epoch in the estimation of this little known and, instead, much maligned neurosis. For this reason, with Professor Charcot's assent, I have altered the book's title, which is in French: '*Leçons sur les maladies du système*

1 [As explained in the Paris Report (p. 7 above), a Chair of Neuropathology had been established for Charcot at the Salpêtrière and facilities there for the study of the neuroses had been greatly extended.]

nerveux, Tome troisième', and brought hysteria into prominence among the subjects with which it deals.

[22] Anyone who is encouraged by these lectures to enter further into the French school's researches on hysteria may be referred to P. Richer's *Études cliniques sur la grande hystérie*, of which a second edition appeared in 1885 and which is in more than one respect a noteworthy volume.

Vienna, July 18, 1886

OBSERVATION OF A SEVERE CASE OF HEMIANAESTHESIA IN A HYSTERICAL MALE

(1886)

EDITORS' NOTE

BEOBACHTUNG EINER HOCHGRADIGEN HEMIANÄSTHESIE BEI EINEM HYSTERISCHEN MANNE

GERMAN EDITIONS

1886 *Wien. med. Wschr.*, **36** (49), 1633–8. (December 4.) [24]
1987 *GW*, **Nachtr.**, 57–64.
2015 *SFG*, **2**, 63–76.

ENGLISH TRANSLATION

1966 *SE*, **1**, 25–31. (Tr. James Strachey.)

The present translation is a revised reprint of the *SE* version. It was apparently intended that this should be the first of a series of papers, since there is a superscription which reads '*Beiträge zur Kasuistik der Hysterie*, I' ('Contributions to the Clinical Study of Hysteria, I'). But the series was not continued.

On October 15, 1886, some six months after his return from Paris, Freud read a paper before the Vienna 'Gesellschaft der Ärzte' (Society of Medicine) with the title 'Über männliche Hysterie' ('On Male Hysteria'). The text of this paper has not survived, though reports of it appeared in the Vienna medical periodicals: for instance, in the *Wien. med. Wschr.*, **36** (43), 1445 f. (see Freud, 1886*g*). It is also briefly summarized by Ernest Jones (1953, 252). Freud himself gives an account of the occasion in his *Autobiographical Study* (1925*d*), *RSE*, **20**, 12. The paper was not well received, and Meynert challenged Freud to present a case of male hysteria before the society. He met with some difficulty in finding one, since the senior physicians of the departments in the General Hospital refused to allow him to use their material. Eventually, with the help of a young laryngologist, he found a suitable patient elsewhere, and presented him before the 'Gesellschaft der Ärzte' on November 26, 1886. The case was demonstrated by Freud and by his friend Dr Königstein,[1] the ophthalmic surgeon, who had made an examination of the patient's eye symptoms. The latter's paper was printed in the *Wochenschrift* a week later than Freud's – in the issue of

1 Leopold Königstein (1850–1924), Professor of Ophthalmology in Vienna. He played a part in the cocaine episode (see Freud, 1925*d*; *RSE*, **20**, 12) and featured in the 'Dream of the Botanical Monograph' (ibid., **4**, 149 ff.). Freud contributed a paper, 'The Psychoanalytic View of Psychogenic Disturbance of Vision' (1910*i*), to a *Festschrift* for Königstein.

December 11 (1674–6). For an English translation of it, see *NSW*, **4** (where Freud's paper is also reprinted). Freud tells us that the present paper met with a better reception than its predecessor, but nevertheless failed to arouse interest.

The greater part of the paper, it will be seen, is concerned with the physical phenomena of hysteria, on the lines characteristic of Charcot's attitude to the condition. There are only some very slight indications of an interest in psychological factors.

OBSERVATION OF A SEVERE CASE OF HEMIANAESTHESIA IN A HYSTERICAL MALE

Gentlemen, when, on October 15, I had the honour of claiming your [25]
attention to a short report on Charcot's recent work in the field of male hysteria, I was challenged by my respected teacher, Hofrat Professor Meynert, to present before the Society some cases in which the somatic indications of hysteria – the 'hysterical stigmata' by which Charcot characterizes this neurosis – could be observed in a clearly marked form. I am meeting this challenge today – insufficiently, it is true, but so far as the clinical material at my disposal permits – by presenting before you a hysterical man, who exhibits the symptom of hemianaesthesia to what may almost be described as the highest degree. Before beginning my demonstration, I will merely remark that I am far from thinking that what I am showing you is a rare or peculiar case. On the contrary, I regard it as a very ordinary case of frequent occurrence, though one which may often be overlooked.

For this patient I have to thank the kindness of Dr von Beregszászy, who sent him to me for confirmation of his diagnosis. The patient is a 29-year-old engraver, August P., now before you: an intelligent man, who readily offered himself for my examination in the hope of an early recovery.

Allow me to begin with an account of his family history and of his life story. The patient's father died, at the age of 48, of Bright's disease; he was a cellar-man, a heavy drinker and a man of violent temper. His mother died, at the age of 46, of tuberculosis. She is said to have suffered much from headaches in earlier years; the patient has nothing to say of attacks of convulsions or anything of the sort. This couple were the parents of six sons, of whom the first led an irregular life and succumbed to a syphilitic cerebral affection. The second son is of special interest for us; he plays a part in the aetiology of his brother's illness and seems to have been a hysteric himself. For he told our patient that he had suffered from attacks of convulsions; and, by a strange coincidence, this very day I met a Berlin colleague who treated this brother in Berlin during an

illness and had diagnosed him as suffering from hysteria – a diagnosis which was also confirmed in a hospital there. The third son is a deserter
[26] from the army and has since disappeared; the fourth and fifth died at an early age, and the last is our patient himself.

Our patient developed normally in his childhood, he never suffered from infantile convulsions and went through the usual children's diseases. In his eighth year he had the misfortune of being run over in the street; he sustained a rupture of the right eardrum, with permanent impairment of hearing in the right ear, and he fell sick of an illness which lasted for several months, during which he suffered frequently from fits, the nature of which it is no longer possible to discover today. These fits continued for some two years. To this accident dates back a slight intellectual dullness which the patient claims to have noticed in his progress at school, and a tendency to feelings of giddiness whenever he was unwell for any reason. Later, he completed his schooling and, after his parents' death, was apprenticed to an engraver; and it speaks very favourably for his character that he remained a journeyman with the same master for ten years. He pictures himself as a person whose thoughts were wholly and solely directed to perfection in his skilled craft, who with that end in view did much reading and drawing and denied himself all social intercourse and all entertainments. He was obliged to reflect a great deal about himself and his ambition, and in doing so often fell into a state of an excited flight of ideas, in which he became alarmed about his mental health; his sleep was often disturbed, his digestion was slowed down by his sedentary way of life. He has suffered from palpitations for the last nine years; but otherwise he was healthy and never interrupted in his work.

His present illness dates back for some three years. At that time he fell into a dispute with his dissolute brother, who refused to pay him back a sum of money he had lent him. His brother threatened to stab him and ran at him with a knife. This threw the patient into indescribable fear [*Angst*][T]; he felt a ringing in his head as though it was going to burst; he hurried home without being able to tell how he got there, and fell to the ground unconscious in front of his door. It was reported afterwards that for two hours he had the most violent spasms and had spoken during them of the scene with his brother. When he woke up, he felt very feeble; during the next six weeks he suffered from violent left-sided headaches and intracranial pressure. The feeling in the left half of his body seemed to him altered, and his eyes got easily tired at his work, which he soon took up again. With a few oscillations, his condition remained like this

for three years, until, seven weeks ago, a fresh agitation brought on a change for the worse. The patient was accused by a woman of a theft, had violent palpitations, was so depressed for about a fortnight that he [27] thought of suicide, and at the same time a fairly severe tremor set in in his left extremities. The left half of his body felt as though it had been affected by a slight stroke; his eyes became very weak and often made him see everything grey; his sleep was interrupted by terrifying apparitions and by dreams in which he thought he was falling from a great height; pains started in the left side of his throat, in his left groin, in the sacral region and in other areas; his stomach was often 'as though it was blown out', and he found himself obliged to stop working. A further worsening of all these symptoms dates from the last week. In addition, the patient is subject to violent pains in his left knee and his left sole if he walks for some time; he has a peculiar feeling in his throat as though his tongue was fastened up, he has frequent singing in his ears, and more of the same sort. His memory is impaired for his experiences during his illness, but is good for earlier events. The attacks of convulsions have been repeated from six to nine times during the three years; but most of them were very slight; only *one* attack at night last August was accompanied by fairly severe 'shaking'.

And now to consider the patient – a rather pale man of mediumly powerful development. The examination of his internal organs reveals nothing pathological apart from dull cardiac sounds. If I press on the point of exit of the supraorbital, infraorbital or mental nerves on the left side, the patient turns his head with an expression of severe pain. There is therefore, we might suppose, a neuralgic change in the left trigeminal. The cranial vault too is very susceptible to percussion in its left half. The skin of the left half of the head behaves, however, quite differently to our expectation: it is completely insensitive to stimuli of any kind. I can prick it, pinch it, twist the lobe of the ear between my fingers, without the patient even noticing the touch. Here, then, there is a very high degree of anaesthesia; but this affects not merely the skin but also the mucous membranes, as I will show you in the case of the patient's lips and tongue. If I insert a small roll of paper into his left external auditory meatus and then through his left nostril, no reaction is produced. I now repeat the experiment on the right side and show that there the patient's sensibility is normal. In accordance with the anaesthesia, the sensory reflexes, too, are abolished or reduced. Thus I can introduce my finger and touch all the pharyngeal tissues on the left side without the result being retching; the pharyngeal reflexes on the right side are, however,

also reduced; only when I reach the epiglottis on the right side is there a
[28] reaction. Touching the left conjunctiva palpebrarum and bulbi produces scarcely any closure of the lids; on the other hand, the corneal reflex is present, though very considerably reduced. Incidentally, the conjunctival and corneal reflexes on the right side are also reduced, though only to a lesser degree; and this behaviour of the reflexes is enough to enable me to conclude that the disturbances of vision need not be limited to the one (left) eye. And in fact, when I examined the patient for the first time, he exhibited in both eyes the peculiar polyopia monocularis of hysterical patients and disturbances of the colour sense. With his right eye he recognized all the colours except violet, which he named as grey; with his left eye he recognized only a light red and yellow, while he regarded all the other colours as grey if they were light and black if they were dark. Dr Königstein was kind enough to submit the patient's eyes to a thorough examination and will himself report later on his findings. [See p. 23 f. above.] Turning to the other sense organs, smell and taste are entirely lost on the left side. Only hearing has been spared by the cerebral hemianaesthesia. It will be recalled that the efficiency of his right ear has been seriously impaired since an accident to the patient at the age of eight; his left ear is the better one; the reduction in hearing present in it is (according to a kind communication from Professor Gruber) sufficiently explained by a visible material affection of the tympanic membrane.

If we now proceed to an examination of the trunk and extremities, here again we find an absolute anaesthesia, in the first place in the left arm. As you see, I can push a pointed needle through a fold of the skin without the patient reacting against it. The deep parts – muscles, ligaments, joints – must also be insensitive to an equally high degree, since I can twist the wrist joint and stretch the ligaments without provoking any feeling in the patient. It tallies with this anaesthesia of the deep parts that the patient, if his eyes are bandaged, also has no notion of the position of his left arm in space or of any movement that I perform with it. I bandage his eyes and then ask him what I have done with his left hand. He cannot tell. I tell him to take hold of his left thumb, elbow, shoulder, with his right hand. He feels about in the air, will perhaps take my hand, which I offer him, for his own, and then admits that he does not know whose hand he has hold of.

It must be especially interesting to find out whether the patient is able to find the parts of the left half of his face. One would suppose that this would offer him no difficulties, since, after all, the left half of his face is,

so to speak, firmly cemented to the intact right half. But experiment shows the contrary. The patient misses his aim at his left eye, the lobe of [29]
his left ear, and so on; indeed he seems to find his way about worse in groping with his right hand for the anaesthetic parts of his face than if he were touching a part of someone else's body. The blame for this is not a disorder in his right hand, which he is using for feeling about, for you can see with what certainty and speed he finds the spot when I tell him to touch places in the right half of his face.

The same anaesthesia is present in his trunk and left leg. We observe there that the loss of sensation has its limit at the mid-line or extends a trace beyond it.

Special interest seems to me to lie in the analysis of the disturbances of movement which the patient exhibits in his anaesthetic limbs. I believe that these disturbances of movement are to be ascribed wholly and solely to the anaesthesia. There is certainly no paralysis – of his left arm, for instance. A paralysed arm either falls limply down or is held rigid by contractures in forced positions. Here it is otherwise. If I bandage the patient's eyes, his left arm remains in the position it had taken up before. The disturbances of mobility are changeable and depend on several conditions. At first, those of you who noticed how the patient undressed himself with both hands and how he closed his left nostril with the fingers of his left hand will not have formed an impression of any serious disturbance of movement. On closer observation it will be found that the left arm, and in particular the fingers, are moved more slowly and with less skill, as though they are stiff, and with a slight tremor. But every movement, even the most complicated, is performed and this is always so if the patient's attention is diverted from the organs of movement and directed solely to the aim of the movement.[1] It is quite otherwise if I tell him to carry out separate movements with his left arm without any remoter aim – for instance, to bend his arm at the elbow joint while he follows the movement with his eyes. In that case his left arm appears much more inhibited [*gehemmter*][T] than before, the movement is per- *Hemmung*
formed very slowly, incompletely, in separate stages, as though there were a great resistance [*Widerstand*] to be overcome, and is accompanied by a lively tremor. The movements of the fingers are extraordinarily weak in these circumstances. A third kind of disturbance of movement, and the severest, is exhibited, finally, if he is expected to carry out separate movements with closed eyes. Something results, to be sure, with the limb which is absolutely anaesthetic, for, as you see, the motor

1 [Cf. in this connection a footnote to Appendix C to the 'Project', p. 419 *n.* 1 below.]

innervation is independent of any sensory information such as normally
[30] flows in from a limb that is to be moved; this movement, however, is minimal, not in any way directed to a particular segment, and not determinable in its direction by the patient. Do not assume, however, that this last kind of disturbance of movement is a necessary consequence of anaesthesia; precisely in this respect far-reaching *individual* differences are to be found. We have observed anaesthetic patients at the Salpêtrière who, if their eyes were closed, retained a much more far-reaching control over a limb that was lost to consciousness.[1]

The same influence of diverted attention and of looking applies to the left leg. For a good hour today the patient walked along the streets with me at a rapid pace, without looking at his feet as he walked. And all I could notice was that he put his left foot down turning it rather outwards and that he often dragged it along the ground.[2] But if I *command* him to walk, then he has to follow every movement of his anaesthetic leg with his eyes, and the movement occurs slowly and uncertainly and tires him very soon. Finally, with his eyes closed he walks altogether uncertainly, and he pushes himself along with both feet staying on the ground, as one of us would do in the dark on unknown territory. He also has great difficulty in remaining upright on his left leg only; if he shuts his eyes in that position, he immediately falls down.

I will go on to describe the behaviour of his reflexes. They are in general brisker than the normal, and, moreover, show little consistency with one another. The triceps and flexor reflexes are decidedly brisker in the right, non-anaesthetic extremity. The patellar reflex seems brisker on the left; the Achilles tendon reflex is equal on both sides. It is also possible to elicit a slight patellar response which is more clearly observable on the right. The cremasteric reflexes are absent; on the other hand the abdominal reflexes are brisk, and the left one immensely increased, so that the lightest stroking of an area of the abdominal skin provokes a maximal contraction of the left rectus abdominis.

In accordance with a hysterical hemianaesthesia, our patient exhibits, both spontaneously and on pressure, painful areas on what is otherwise the insensitive side of his body – what are known as 'hysterogenic zones',[3]
[31] though in this case their connection with the provoking of attacks is not

1 Cf. Charcot, 1886. [The reference is to a case reported in Lecture XXII of the volume of Charcot's lectures which Freud had just translated; see in particular page 295 of the German version (Freud, 1886*f*).]

2 [This characteristic is the subject of a footnote in Freud's French paper on organic and hysterical paralyses (1893*c*), p. 190 below.]

3 [See the account of these in the article on 'Hysteria' (1888*b*), pp. 45–6 below.]

marked. Thus the trigeminal nerve, whose terminal branches, as I showed you earlier, are sensitive to pressure, is the seat of a hysterogenic zone of this kind; also a narrow area in the left medial cervical fossa, a broader strip in the left wall of the thorax (where the skin too is still sensitive), the lumbar portion of the spine and the middle portion of the os sacrum (the skin is sensitive over the former of these as well). Finally, the left spermatic cord is very sensitive to pain, and this zone is continued along the course of the spermatic cord into the abdominal cavity to the area which in women is so often the site of 'ovaralgia'.

I must add two remarks relating to deviations of our case from the typical picture of hysterical hemianaesthesia. The first is that the right side of the patient's body is also not free from anaesthesia, though this is not of a high degree and seems to affect only the skin. Thus there is a zone of reduced sensitivity to pain (and feeling of temperature) over the dome of the right shoulder, another passes in a band round the peripheral end of the lower arm; the right leg is hypaesthetic on the outer side of the thigh and on the back of the calf.

A second remark relates to the fact that the hemianaesthesia in our patient exhibits very clearly the characteristic of instability. Thus, in a test for electrical sensitivity, contrary to my intention, I made a piece of skin at the left elbow sensitive; and repeated tests showed that the extent of the painful zones on the trunk and the disturbances of the sense of vision oscillated in their intensity. It is on this instability of the disturbance of sensitivity that I found my hope of being able to restore the patient in a short time to normal sensitivity.

THREE SHORT REVIEWS

(1887)

THREE SHORT REVIEWS[1]

Review of Averbeck's 'Die akute Neurasthenie'[2]

How little the so-called clinical education acquired in our hospitals suffices for the needs of practical physicians is most strikingly shown, perhaps, from the example of 'neurasthenia'. That pathological condition of the nervous system may comfortably be described as the commonest of all the diseases in our society: it complicates and aggravates most other clinical pictures in patients of the better classes and it is either still quite unknown to the many scientifically educated physicians or is regarded by them as no more than a modern name with an arbitrarily compounded content. Neurasthenia is not a clinical picture in the sense of textbooks based too exclusively on pathological anatomy: it should rather be described as a mode of reaction of the nervous system.[3] It would deserve the most general attention on the part of physicians who are working scientifically – no less attention than it has already found among physicians who are working as therapists, among directors of sanatoria, etc. A recommendation to wider circles is therefore the due of the present short work, with its felicitous, though intentionally high-pitched, descriptions and its proposals and observations touching on social conditions. These, as its author suspects, will not always meet with his colleagues' agreement, though it will everywhere arouse their interest. His remark on compulsory military service as a cure for the evils [35]

1 [During the period after Freud's return to Vienna from Paris he did a certain amount of reviewing for medical periodicals. Three of the reviews, which are translated here, are the only ones that have been found which deal with psychological topics; the others are of a neurological character. The present review was reprinted in *GW*, **Nachtr.**, 65–6, and *SFG*, **2**, 182–3. The translation (by James Strachey) first appeared in *SE*, **1**, 35.]

2 [*Wien. med. Wschr.*, **37** (5), 138. (January 29, 1887.) *Die akute Neurasthenie, ein ärztliches Kulturbild*, Berlin, 1886. J. H. Averbeck (1844–89) was a specialist in physical therapies. He practised in Bremen and Baden-Baden but also owned a sanatorium in Laubach. He published several essays on social-medical and political questions. The full title of the work reviewed here was 'Acute Neurasthenia – Sudden Exhaustion of Nervous Energy: A Medical-Social Picture'.]

3 [Freud was generally critical of a narrowly localizationist approach to neuropsychology; see Freud, 1891*b*; *NSW*, **4**.]

of civilized life and his proposal that periodic recuperation should be made possible for the working middle class in times of good health by *State* assistance – these are open to manifold objections. It must be admitted, however, that the booklet treats important questions of medical care in an imaginative manner.

DR SIGM. FREUD

Review of Weir Mitchell's 'Die Behandlung gewisser Formen von Neurasthenie und Hysterie'[1]

[36] The therapeutic procedure proposed by Weir Mitchell,[2] the highly original nerve specialist in Philadelphia, was first recommended in Germany by Burkart[3] and has been given full recognition during the last year in a lecture by Leyden.[4] This procedure, by a combination of rest in bed, isolation, feeding-up, massage and electricity in a strictly regulated manner, overcomes severe and long-established states of nervous exhaustion. It is Leyden, too, who was responsible for arranging the translation of the present short volume. It contains the most valuable advice for the selection of cases suitable for the treatment in question and some interesting remarks on the operation of the different therapeutic forces which compose the Weir Mitchell treatment. It will no doubt bring a widening of his knowledge to every physician. The specifically English arrangement of the sentences and thoughts has perhaps been preserved too exactly in the translation. The terms 'hysteria' and 'hysterical' are

1 [*Wien. med. Wschr.*, **37** (5), 138. (January 29, 1887.) *Die Behandlung gewisser Formen von Neurasthenie und Hysterie* ('The treatment of certain forms of neurasthenia and hysteria') by S. Weir Mitchell, translated by Dr G. Klemperer. Berlin: Aug. Hirschwald, 1887. In its American original this volume bears the title *Fat and Blood and How to Make Them*: in some of its many editions there is a subtitle with the words used in the German title above. Freud's review was reprinted in *GW*, **Nachtr.**, 67–8, and *SFG*, **2**, 184–5. The present translation (by James Strachey) is a reprint of the one first published in *SE*, **1**, 36. – It may be recalled that at this period Freud himself made use of the Weir Mitchell treatment, and writes very favourably of the result of combining it with cathartic treatment. Cf. the end of Section (1) of Freud's technical contribution to *Studies on Hysteria* (1895*d*), *RSE*, **2**, 237 f.]

2 [Silas Weir Mitchell (1829–1914), physician and neurologist, was known, in particular, for his 'rest cure'.]

3 [Rudolf Burkart (b. 1846) was chief physician at the Johannes Hospital in Bonn.]

4 [Ernst Viktor von Leyden (1832–1910) was professor at Berlin University and specialized in nutritional therapy.]

employed for the most part in the vulgar and not in the scientific sense of that much-abused word.

DR SIGM. FREUD

Review of Berkhan's 'Deaf-Mutism'[1]

This contribution will not fail to arouse sensation, and to commend anew the writings of the original researcher Braid[2] – the father of hypnotism – to the physician. Starting from Braid's [1843] assertions that he could restore, at least partially, the power of hearing to several congenitally deaf people by placing them under hypnosis, Berkhan entered into collaboration with deaf-mutism specialists to replicate such experiments. Several boys, whose total deafness was established prior to the experiments, were hypnotized by having them stare into a shiny glass ball. Hypnosis was achieved in five to nine minutes. During this period various vocalizations were shouted into the boys' ears, and they were exposed to ringing, whistling, etc. After eight days had passed, the hypnosis was repeated – four to six times in all with each individual. After the hypnosis the boys' hearing was retested, and it was ascertained that a few were capable of hearing some vocalizations, the chime of a tower-clock, the whistling of a train, etc. The gain was an enduring one; it was still noticeable, in one case, one and a half years after the experiments were conducted. *The enormous increase in the excitability of sensory centres through hypnosis*, which has been demonstrated in the Salpêtrière by Charcot [1882], *makes these results understandable*. With some deaf-mute boys, however, as Berkhan candidly reports, he achieved no success.

FREUD (VIENNA)

1 [*Zbl. Kinderheilk.*, **1** (2) (March 19, 1887), 36–7. Berkhan's paper 'Versuche, die Taubstummheit zu bessern und die Erfolge dieser Versuche' ('Experiments into the Amelioration of Deaf-Mutism and the Results of these Experiments') was published in *Berl. klin. Wschr.*, **24** (6) (1887), 96. This short review was discovered by Gerhard Fichtner and reprinted by him, very slightly abridged, in *Med. hist. J.*, **22** (1987), 246–62. It was then reprinted in full in *GW*, **Nachtr.** (1987), 103–4, *SFG*, **2**, 131–2. An English translation (by Mark Solms) was published in 1990 in *Int. Rev. Psychoanal.*, **17** (3), 365. The present translation is a slightly modified reprint of the one published in 1990. This was Freud's very first publication on hypnotism. – Oswald Berkhan (1834–1917) was a physician with interest in mental deficiency and speech disorders.]

2 [James Braid (1795–1860) was a Scottish physician who may perhaps be regarded as the first truly scientific student of hypnotism. He introduced the term in 1843.]

HYSTERIA

GERMAN EDITIONS

1888 In *Handwörterbuch der gesamten Medizin*, ed. A. Villaret, Stuttgart, **1**, 886–92. [39]
1953 *Psyche*, **7** (9), 486–500.
1987 *GW*, **Nachtr.**, 72–92.
2015 *SFG*, **2**, 243–60.

ENGLISH TRANSLATION

1966 *SE*, **1**, 41–59. (Tr. James Strachey.)

The present translation is a revised and corrected reprint of the *SE* version.

In two of Freud's letters to Fliess published in the *Anfänge* (1950*a*), of May 28 (Letter 4) and August 29 (Letter 5) both of 1888 – and, by implication, in a third, of November 24, 1887 (Letter 1) – he speaks of his contributions to Villaret's encyclopaedia, a work published in two volumes (1888 and 1891). Since the articles in Villaret are unsigned, it is not possible to be completely sure of their authorship. Freud himself specifies only one of them in these letters – that on cerebral anatomy – and complains that it has been very much cut down; but in his *Autobiographical Study* (1925*d*) he further mentions an article on aphasia, *RSE*, **20**, 15. The evidence supporting Freud's authorship of these two articles is summarized by Solms & Saling (1990). The editors of the *Anfänge* suggest in addition that articles on infantile palsies and on paralyses might be attributed to him, and, with more conviction, include as probably by Freud the one on hysteria which follows below.[1] Vogel (1974) and Reicheneder (1990) further suggest that some of the entries on cranial nerve and other nuclei as well as the article on localization may be attributed to Freud. Subsequent research by Anneliese Menninger (2011) shows conclusively that the latter article and the second part of the article on cerebral anatomy (the part on cerebral physiology) were in fact written by Johannes Gad. She and Vogel (1974) also refute Freud's authorship of the article on infantile spinal paralysis. For a full discussion of this entire issue, see the

1 Another very much shorter article, on hystero-epilepsy, is less obviously by Freud, though a footnote to it seems most likely to be his. We have included this article in an Appendix below (p. 61).

editor's notes to the English translations of the articles in question in the *NSW* (Freud, 1888*b*, 1888*c*, 1888*z*, 1891*c*).

The 1953 reprint of this article in *Psyche*, the German periodical, is preceded by a short paper by Professor Paul Vogel which gives an admirable and convincing summary of the arguments for believing that this article is indeed by Freud. No-one who reads it together with Freud's contemporary writings can feel doubt as to its authorship.[1] Apart from a whole series of duplications of views expressed by Freud elsewhere in his signed works, there is one particular point which seems conclusive. This is a passage towards the end in which the cathartic method of treatment is
[40] explicitly described and is attributed to Breuer. At this date (1888) Breuer's method had not been published either by himself or by anyone else. Its first publication was in the Breuer & Freud 'Preliminary Communication' more than four years later (1893*a*). Freud, as he tells us (1925*d*), *RSE*, **20**, 16, had long been in Breuer's confidence and had known of his method even before going to Paris (in 1885). Thus Freud's authorship may be taken as established.[2]

The article as a whole shows Freud still closely following the doctrines of Charcot in his account of hysteria, though, quite apart from the reference to Breuer, there are two or three passages, especially towards the end of the article, in which there are clear signs of a more independent attitude.

1 The one possible question is raised by an apparent misrepresentation of Charcot's views on p. 45 below.

2 Incidentally, this passage serves further to demolish the myth, which is still met with, that the cathartic method originated with Pierre Janet, whose book, which included similar notions, was published in 1889 and so seemed to give him a technical priority over Breuer. The present reference in 1888, which has, oddly enough, usually been overlooked, finally disposes of this claim. But in all this discussion weight must be allowed to Andersson's view, which is very briefly indicated in a footnote below on p. 59.

HYSTERIA

HYSTERIA (*ὑστέρα*, womb); (French, *hystérie*; English, *hysterics* [*sic*]; Italian, *isteria*, f., *isterismo*, m.). [41]

I. HISTORY

The name 'hysteria' originates from the earliest times of medicine and is a precipitate of the prejudice, overcome only in our own days, which links neuroses with diseases of the female sexual apparatus. In the Middle Ages neuroses played a significant part in the history of civilization; they appeared in epidemics as a result of psychical contagion, and were at the root of what was factual in the history of possession and of witchcraft. Documents from that period prove that their symptomatology has undergone no change up to the present day. A proper assessment and a better understanding of the disease only began with the works of Charcot and of the school of the Salpêtrière inspired by him. Up to that time hysteria had been the *bête noire* of medicine. The poor hysterics, who in earlier centuries had been burnt or exorcized, were only subjected, in recent, enlightened times, to the curse of ridicule; their states were judged unworthy of clinical observation, as being simulation and exaggerations.

Hysteria is a neurosis in the strictest sense of the word – that is to say, not only have no perceptible changes in the nervous system been found in this illness, but it is not to be expected that any refinement of anatomical techniques would reveal any such changes. Hysteria is based wholly and entirely on physiological modifications of the nervous system and its essence should be expressed in a formula which took account of the conditions of excitability [*Erregbarkeitsverhältnissen*][T] in the different parts of the nervous system.[1] A physiopathological formula of this kind has not yet, however, been discovered; we must be content meanwhile

Erregung

1 [See footnote 3, p. 35 above. In large part, Freud's 1895 'Project' (1950*a*, p. 307 ff. below) represents his attempt to find a physiopathological formula of the kind he alludes to here.]

to define the neurosis in a purely nosographical fashion by the totality of symptoms occurring in it, in the same sort of way as Graves' disease is characterized by a group of symptoms – exophthalmos, struma, tremor, acceleration of the pulse and psychical change – without any consideration of the closer connection between these phenomena.[1]

II. DEFINITION

German, as well as English, authorities are still in the habit today of allotting the descriptions 'hysteria' and 'hysterical' capriciously, and of throwing 'hysteria' into a heap along with general nervousness, neurasthenia, many psychotic states and many neuroses which have not yet [42] been picked out from the chaos of nervous diseases. Charcot, on the contrary, holds firmly to the view that 'hysteria' is a sharply circumscribed and well-defined clinical picture, which may be most clearly recognized in the extreme cases of what is known as '*grande hystérie*' [major hysteria] (or hystero-epilepsy).[2] Hysteria also covers the milder and rudimentary forms which occur in a series gradually shading off from the type of *grande hystérie* to the normal. Hysteria is fundamentally different from neurasthenia and indeed, strictly speaking, is contrary to it.

III. SYMPTOMATOLOGY

The extremely rich, but not at all on that account anarchical, symptomatology of 'major hysteria' is composed of a series of symptoms which include the following:

(1) *Convulsive attacks*. These are preceded by a peculiar 'aura': pressure in the epigastrium, constriction in the throat, throbbing in the temples, ringing in the ears, or components of this complex of feelings. These aura sensations, as they are called, also appear in hysterical patients on their own account or represent an attack in themselves alone. Especially well known is the *globus hystericus*, a feeling referable to spasms of the pharynx, as though a lump were rising up from the epigastrium to the

1 [The purely nosographic approach was a hallmark of Charcot's school of neuropathology, as opposed to the theoretical-explanatory approach of the German-speaking school. Cf. Freud's comments in his (1892–94*a*) Preface to Charcot's *Tuesday Lectures*, pp. 162–3 below.]

2 [See, however, the footnote to the article on hystero-epilepsy quoted below (p. 61 *n.* 2).]

throat. An attack proper, if it is complete, manifests three phases.[1] The first, 'epileptoid', phase resembles a common epileptic fit, occasionally a unilateral epileptic fit. The second phase, that of the '*grands mouvements*', manifests movements of wide compass, such as what are known as 'salaam' movements, arched attitudes (*arc de cercle*), contorsions and so on. The strength developed in these is often quite immense. To distinguish these movements from an epileptic fit, it may be remarked that hysterical movements are always performed with an elegance and coordination, which is in strong contrast to the clumsy coarseness of epileptic spasms. Moreover, comparatively severe injuries are for the most part avoided even in the most violent hysterical convulsions. The third, *hallucinatory*, phase of a hysterical attack, the '*attitudes passionnelles*', is distinguished by attitudes and gestures which belong to scenes [43]
of passionate movement, which the patient hallucinates and often accompanies with the corresponding words. During the entire attack consciousness may either be retained or be lost – more often the latter. Attacks of the kind described are often linked together in a series, so that the whole attack may last for several hours or days. The rise in temperature during them is (in contrast to what happens in epilepsy) insignificant. Each phase of the attack or each separate portion of a phase may be isolated and may stand for the attack in rudimentary cases. We naturally come across abbreviated attacks of this kind incomparably more often than complete ones. Of special interest are those hysterical attacks which, instead of the three phases, exhibit a coma appearing in an apoplectiform manner – the so-called '*attaques de sommeil*' [attacks of sleep]. This coma may resemble natural sleep, or may be accompanied by so great a reduction of respiration and circulation as to be taken for death. There are authenticated instances of states of this sort lasting for weeks and months; in such prolonged sleep bodily nutrition gradually diminishes, but danger to life is not involved. – In about a third of the cases of hysteria the symptom of attacks, which is so characteristic, is absent.

(2) *Hysterogenic zones*. Intimately connected with attacks we find what are called 'hysterogenic zones', supersensitive areas of the body, on which a slight stimulus releases an attack, the aura of which often starts

1 [Charcot usually specifies *four* phases for major hysterical attacks. See, for instance, Sketch C below, p. 179, and the 'Preliminary Communication' (1893*a*) itself, *RSE*, **2**, 12. Charcot is not always so definite, and the fourth phase (the 'terminal delirium') seems sometimes to be omitted. Cf. his differing accounts in works translated by Freud: Freud, 1886*f*, 212 ('four sharply distinguished periods'), and Freud, 1892–94*a*, 135 ('the whole series of three phases').]

with a feeling from this area. These areas may be situated in the skin, in the deep parts, the bones, the mucous membranes, even in the sense organs. They are found more often on the trunk than on the extremities, and they have a predilection for certain places – for instance, in women (and even in men)[1] in an area of the abdominal wall corresponding to the ovaries, in the crown of the head and the region under the breast, and in men in the testes and spermatic cord. Pressure on these areas often releases, not a convulsion, but aura sensations. It is also possible to exercise an inhibiting influence from many of these hysterogenic zones upon convulsive attacks; exerting strong pressure on the ovarian area, for instance, rouses many patients from the middle of a hysterical attack or from hysterical sleep. In the case of such patients one can guard against a threatening attack by making them wear a belt like a truss, the pad of which presses on the ovarian area. The hysterogenic zones are sometimes numerous, sometimes few, and may be unilateral or bilateral.

[44] (3) *Disturbances of sensibility*. These are the most frequent indications of the neurosis and the most important diagnostically. They persist even during periods of remission and are the more important because disturbances of sensibility play a relatively small part in organic brain diseases. They consist in *anaesthesia* or *hyperaesthesia*, and exhibit the greatest freedom in their extent and their degree of intensity, such as is attained in no other disease. Anaesthesia may affect the skin, mucous membranes, bones, muscles and nerves, sense organs and intestines; but the commonest is anaesthesia of the skin. In the case of *hysterical anaesthesia of the skin* all the different sorts of skin sensation can be dissociated and can behave quite independently of one another. The anaesthesia may be total or may affect only the feeling of pain (analgesia – which is the most common), or only sensations of temperature, pressure or electricity, or muscular sense. Only one possibility is not realized in hysteria: an impairment of the sense of touch while the other qualities are retained. On the other hand it may happen that pure tactile sensations give rise to a painful impression (*alphalgesia*). Hysterical anaesthesia often attains such a high degree that the most powerful faradization of nerve trunks produces no sensory reaction. In extent the anaesthesia may be total; in rare cases it may affect the whole surface of the skin and the majority of the sense organs. More often, however, it is a *hemianaesthesia*, like that produced by injury to the internal capsule; but it is distinguished from hemianaesthesia due to organic disease by the fact that it usually

1 [See the case demonstrated by Freud, p. 31 above.]

oversteps the mid-line at some point – for instance, that it includes the tongue, larynx or genitals as a whole – and that the eyes are not affected in the form of hemianopsia, but as amblyopia or as amaurosis of one eye. Furthermore, hysterical hemianaesthesia has greater freedom in the form of its distribution; it may happen that one sense organ or one organ on the anaesthetic side may escape the anaesthesia entirely, and any sensible area in the picture of the hemianaesthesia may be replaced by the symmetrical area on the other side (spontaneous *transfert*, see below [p. 51]). Finally, hysterical anaesthesia may appear in disseminated foci, unilateral or bilateral, or merely in certain areas, monoplegic on the extremities or in patches over diseased internal organs (pharynx, stomach, etc.).

In all of these relations it can be replaced by hyperaesthesia. – In the case of hysterical anaesthesia the sensory reflexes are as a rule reduced – for instance, the conjunctival, sternutatory and pharyngeal reflexes; but the vital corneal and glottis reflexes are retained. The vasomotor reflexes and dilatation of the pupils through stimulation of the skin are not interrupted even when it is subject to the highest degree of anaesthesia. [45]
Hysterical anaesthesia is always a symptom which has to be looked for by the physician, since for the most part, even when it is of wide extent and of great severity, it usually escapes the patient's perception entirely. In contrast to organic anaesthesia, it must be emphasized that hysterical disturbances of sensibility do not as a rule hinder patients in any motor activity. Areas of the skin which are hysterically anaesthetic are often characterized by local anaemia and do not bleed when pricked; this, however, is only a complication and is not a necessary condition of the anaesthesia. It is possible to separate the two phenomena from each other artificially. There is often a reciprocal relation between anaesthesia and hysterogenic zones, as though the whole sensibility of a comparatively large part of the body were compressed into the one zone. – Disturbances of sensibility are the symptoms on which it is possible to base a diagnosis of hysteria, even in its most rudimentary forms. In the Middle Ages the discovery of anaesthetic and non-bleeding areas (*stigmata Diaboli*) was regarded as evidence of witchcraft.

(4) *Disturbances of sensory activity*. These can affect all the sense organs; they may appear simultaneously with or independently of changes in the sensibility of the skin. Hysterical disturbance of vision consists in unilateral amaurosis or amblyopia or in bilateral amblyopia, but never in hemianopsia. Its symptoms are: normal examination of the fundus,

absence of the conjunctival reflex (diminished corneal reflex), concentric narrowing of the field of vision, reduction of light perception, and achromatopsia. In the case of the last-mentioned, the sensation of violet is the first to be lost, the sensation of red or blue persists longest. The phenomena fit in with no theory of colour-blindness; the different sensations of colour behave independently of one another. There are frequent disturbances of accommodation, and false conclusions resulting from them. Objects approaching the eye and moving away from it are seen in different sizes and double or several times (monocular diplopia with macropsia and micropsia). – Hysterical deafness is rarely bilateral, mostly more or less complete, combined with anaesthesia of the auricle, the auditory canal and even of the tympanic membrane. Where there is hysterical disturbance of taste and smell, too, it is as a rule possible to find an anaesthesia of the regions of the skin and mucous membrane belonging to the sense organ. Paraesthesia and hyperaesthesia of the inferior sense organs are frequent in hysterical patients; occasionally there is an extraordinary refinement of sensory activity, particularly of smell and hearing.

[46] (5) *Paralyses*. Hysterical paralyses are rarer than anaesthesia and almost always accompanied by anaesthesia of the paralysed part of the body, whereas in organic illnesses the disturbances of motility preponderate and emerge independently of anaesthesia. Hysterical paralyses take no account of the anatomical structure of the nervous system which, as is well known, shows itself most unambiguously in the distribution of organic paralyses.[1] Above all, there are no hysterical paralyses which could be equated with peripheral facial, radial and serratus paralyses – that is, which comprise groups of muscles or muscle and skin, combined in the way which is determined by a common anatomical innervation. Hysterical paralyses are only comparable with cortical ones, but are distinguished from those by a number of features. For there is such a thing as a hysterical hemiplegia, in which, however, only the arm and leg on the same side are involved: there is no such thing as a hysterical facial paralysis. At most, alongside of the paralysis of the extremities, there may be a spasm of the facial muscles and of the tongue, situated sometimes on the side of the paralysis and sometimes on the opposite side, and manifested among other things by an excessive deviation of the tongue. Another distinctive characteristic of hysterical hemiplegia lies in the fact

1 [This section corresponds to the main topic of Freud's French paper on the comparison between organic and hysterical paralyses (1893*c*), probably written for the most part in the same year as this article (1888), though not published till five years later. See p. 185 below.]

that the paralysed leg is not moved in a circular wheeling motion at the hip but is dragged along like a lifeless appendage.[1] Hysterical hemiplegia is always linked with a hemianaesthesia which is usually of a comparatively severe degree. Furthermore, in hysteria we meet with paralysis of an arm or a leg independently or of both legs (paraplegia). In the latter case paralysis of the bowel and of the bladder may accompany the anaesthesia of the legs and the clinical picture may consequently come closely to resemble a spinal paraplegia. The paralysis, again, instead of extending to a whole limb, may affect sections of it – a hand, shoulder, elbow, etc. In this there is no preference for the terminal portion, whereas it is characteristic of an organic paralysis that it is always more pronounced at the distal portion of the limb than at the proximal portions. In the case of a partial paralysis of a limb the anaesthesia usually observes the same limits as the paralysis, and is circumscribed by lines which are at right angles to the longitudinal axis of the limb. In hysterical paralysis of the [47]
legs the triangle of skin between the gluteal muscles, corresponding to the sacrum, escapes anaesthesia. In all these paralyses, the phenomena of descending degeneration are absent, however long the paralyses may last; there is often a high degree of muscular flaccidity, the behaviour of the reflexes is inconstant; on the other hand, the paralysed extremities may atrophy and indeed they succumb to an atrophy which develops very rapidly, soon comes to a stop and is accompanied by no change in electrical excitability. To the paralyses of the limbs must be added hysterical aphasia, or more correctly dumbness, which consists in an inability to produce any articulate sound or [even] to carry out unvoiced speech movements. It is always accompanied by *aphonia*, which also occurs by itself; ability to write is retained in such cases and even increased. The remaining motor paralyses in hysteria cannot be related to parts of the body but only to functions: e.g. astasia and abasia (inability to walk and to stand); this occurs while the legs retain their sensibility, their coarse power and the capacity for performing any kind of movement when in a horizontal position – a separation of the functions of the same muscles which is not found with organic lesions.[2] All hysterical paralyses are distinguished by the fact that they may be of the greatest severity but at the same time be sharply restricted to a particular part of the body, whereas organic paralyses as a rule extend over a larger area as their severity increases.[3]

1 [Cf. an enlargement of this point in a footnote to the French paper just quoted, p. 190 *n*. below.]

2 [This precise point is made in the French paper, p. 191 below.]

3 [For this, too, cf. the French paper, pp. 191–2 below.]

(6) *Contractures*. In the more serious forms of hysteria there is a general tendency for the muscular apparatus to respond to slight stimuli by contracture (*diathèse de contracture*). The mere application of an Esmarch bandage may be enough for this. Contractures of this kind also occur frequently in less severe cases and in the most various muscles. In the extremities they are characterized by their excessive height and may occur in every position, not explicable by the stimulation of particular nerve trunks. They are uncommonly obstinate, do not, like organic contractures, relax in sleep, nor can their intensity be changed by excitation, temperature, etc. They only yield in the deepest narcosis, and after waking re-establish themselves at their full height. Muscular contractures are very frequent in the other organs, sense organs and intestines and in a number of cases, too, constitute the mechanism by which function is suspended in paralyses. The tendency to clonic spasms is also much increased in hysteria.

[48] (7) *General characteristics*. The symptomatology of hysteria has a number of general characteristics, a knowledge of which is important both for the diagnosis and for the understanding [*Auffassung*][T] of hysteria. Hysterical manifestations have, by preference, the characteristic of being excessive: a hysterical pain is described by patients as extremely painful, an anaesthesia and a paralysis may easily become absolute, a hysterical contracture brings about the greatest retraction of a muscle of which it is capable. At the same time, any particular symptom can occur, so to say, in isolation: anaesthesia and paralysis are not accompanied by the general phenomena which, in the case of organic lesions, give evidence of a cerebral affection and which as a rule by their importance put the localizing symptoms in the shade. Next to an absolutely insensitive area of skin there will be one of absolutely normal sensibility. Along with a totally paralysed arm there will be a perfectly intact leg on the same side. *It is especially characteristic of hysteria for a disorder to be at the same time most highly developed and most sharply limited*. Furthermore, hysterical symptoms shift in a manner which from the outset excludes any suspicion of a material lesion. This shifting of the symptoms is brought about either spontaneously (for instance, after convulsive attacks, which often change the distribution of paralysis and anaesthesia or suspend them) or owing to artificial influence by what are called aesthesiogenic methods: such as electricity, the application of metals, the employment of cutaneous irritants, magnets, etc. This latter method of influence seems all the more remarkable in view of the fact that a hysterical nervous system

offers great resistance as a rule to chemical influence by internal medication and reacts in a positively perverse manner to narcotics such as morphine and chloral hydrate. – Among the means which are capable of removing hysterical symptoms special emphasis must be laid on the influence of excitement [*Erregung*] and of hypnotic suggestion, the latter because it points directly to the mechanism of hysterical disorders and cannot be suspected of producing any but psychical effects. When hysterical symptoms are shifted, some striking circumstances come into prominence. By the use of 'aesthesiogenic' methods it is possible to transfer an anaesthesia, a paralysis, a contracture, a tremor, etc., to the symmetrical area in the other half of the body ('*transfert*'), while the originally diseased area becomes normal. In this way hysteria gives evidence of the symmetrical relation of which moreover there are hints that it plays a part in physiological states as well – just as, in general, neuroses create nothing new but only develop and exaggerate physiological relations. A further and extremely important characteristic of hysterical disorders is that they do not in any way present a copy of the [49]
anatomical conditions of the nervous system. It may be said that hysteria is as ignorant of the science of the structure [*Bau*]^{T} of the nervous system as we ourselves before we have learnt it.[1] The symptoms of organic affections, as is well known, reflect the anatomy of the central organ and are the most trustworthy sources of our knowledge of it. We must for that reason dismiss the thought that some possible organic disorder lies at the root of hysteria; nor must we appeal to vasomotor influences (vascular spasms) as the cause of hysterical disorders. A vascular spasm is from its nature an organic change, the effect of which is determined by anatomical conditions, and it differs from an embolism, for instance, only by the fact that it leads to no *permanent* change.

Alongside of the physical symptoms of hysteria, a number of psychical disturbances are to be observed, in which at some future time the changes characteristic of hysteria will no doubt be found but the analysis of which has hitherto scarcely been begun. These are changes in the passage [*Ablauf*]^{T} and in the association of ideas [*Assoziation von Vorstellungen*]^{T}, inhibitions [*Hemmungen*]^{T} of the activity of the will, magnification and suppression of feelings, etc. – which may be summarized as *changes in the normal distribution over the nervous system of the stable amounts of excitation* [*Erregungsgrössen*]. A psychosis in the psychiatrist's sense of the word is not a part of hysteria, though it can develop on the

1 [This is almost a literal replica of the well-known sentence in the French paper (p. 196 below). – Cf. on '*transfert*' p. 85 below.]

foundation of the hysterical *status* and is then to be regarded as a complication. What is popularly described as a hysterical temperament – instability of will, changes of mood, increase of excitability with a diminution of all altruistic feelings – may be present in hysteria, but is not absolutely necessary for its diagnosis. There are severe cases of hysteria in which a psychical change of that kind is entirely absent; many of the patients who belong to this class are among the most amiable, clear-minded people, with the strongest will, who feel their illness distinctly as something foreign to their nature. The psychical symptoms have their significance in the total picture of hysteria, but they are no more constant than the different physical symptoms, the stigmata. On the other hand, the psychical changes which must be postulated as being the foundation of the hysterical *status* take place wholly in the sphere of unconscious, automatic, cerebral activity. It may, perhaps, further be emphasized that in hysteria the influence of psychical processes on physical processes in the organism (as in all neuroses) is increased and that hysterical patients work with a surplus of excitation in the nervous system – a surplus which
[50] manifests itself, now as an inhibitor, now as an irritant, and is displaced
Verschiebung [*verschiebt*][T] within the nervous system with great freedom.[1]

Hysteria must be regarded as a *status*, a nervous diathesis, which produces outbreaks from time to time. The aetiology of the *status hystericus* is to be looked for entirely in heredity: hysterics are always hereditarily disposed to disturbances of nervous activity, and epileptics, psychical patients, tabetics, etc., are found among their relatives. Direct hereditary transmission [*Übertragung*][T] of hysteria, too, is observed, and is the basis, for instance, of the appearance of hysteria in boys (from their mother). Compared with the factor of heredity all other factors take a second place and play the part of incidental causes, the importance of which is as a rule overrated in practice.[2] The accidental causes of hysteria are, however, to this extent important that they release the onset of hysterical outbreaks, of acute hysterias. As factors calculated to encourage the development of a hysterical disposition may be mentioned:

1 [The conceptions in this paragraph of the importance of the distribution of excitation in the nervous system are familiar in Freud's writings of this period. (See, for instance, the last paragraphs of his introduction to Bernheim, p. 88 f. below.) The final sentence here, on a surplus of excitation acting as an inhibitor or as an irritant, appears to foreshadow the 'principle of constancy'.]

2 [The present passage is a pure statement of Charcot's views with his stress upon heredity, his doctrine of the '*famille névropathique*', and his relegation of all other factors to the rank of '*agents provocateurs*'. Only a few years later Freud was attacking these views – for instance, in his footnotes to Charcot's *Leçons du mardi* (1892–94*a*), p. 170 below, in his obituary of Charcot (1893*f*), *NSW*, **4**; *RSE*, **3**, 20, and lastly in his French paper on 'Heredity and the Aetiology of the Neuroses' (1896*a*), ibid., **3**, 153 ff.]

a mollycoddling upbringing (hysteria in only children), premature awakening of mental [*geistigen*]T activity in children, frequent and violent excitements. All these influences are equally prone to bring about neuroses of other kinds (e.g. neurasthenia), so that the decisive influence of hereditary disposition is strikingly shown in this. As factors which produce outbreaks of acute hysterical illness may be adduced: trauma, intoxication (lead, alcohol), grief, emotion, exhausting illness – anything, in short, which is able to exercise a powerful effect of a detrimental kind. On other occasions hysterical states are often generated by trivial or obscure causes. As regards what is often asserted to be the preponderant influence of abnormalities in the sexual sphere [*Geschlechtssphäre*]T upon the development of hysteria, it must be said that its importance is as a rule overestimated. In the first place, hysteria is found in sexually immature girls and boys, just as, too, the neurosis with all its characteristics also occurs in the male sex, though a great deal more rarely (1:20). Furthermore, hysteria has been observed in women with a complete lack of genitalia,[1] and every physician will have seen a number of cases of hysteria in women whose genitals exhibited no anatomical changes at all, just as, on the contrary, the majority of women with diseases of the sexual organs do not suffer from hysteria. It must, however, be admitted that conditions related *functionally* to sexual life [*Geschlechtsleben*] play a great part in the aetiology of hysteria (as of *all* neuroses), and they do so on account of the high psychical significance of this function especially in the female sex. – Trauma is a frequent incidental cause of hysterical illness, in two directions: firstly, by a hitherto unobserved hysterical disposition being aroused by a powerful physical trauma, which is accompanied by fright and a momentary loss of consciousness, and secondly, by the part of the body affected by the trauma becoming the seat of a local hysteria. Thus, for instance, in hysterical subjects a slight contusion of the hand may be followed by the development of a contracture of the hand, or, in analogous circumstances, a painful coxalgia may develop, and so on. An acquaintance with these obstinate affections is of the greatest importance to surgeons, whose intervention in such conditions can do nothing but harm. Differential diagnosis of these conditions, especially where the joints are affected, is not always easy. Conditions brought about by severe general trauma (railway accidents, etc.), known as 'railway spine' and 'railway brain',[2] are regarded as hysteria by Charcot, with which view American writers, whose authority

on this question is not to be disputed, are in agreement. These states often have the most gloomy and severe appearance; they are combined with depression and a melancholic mood and exhibit, at all events in a number of cases, a combination of hysterical with neurasthenic and organic symptoms. Charcot has also proved that encephalopathy from plumbism is related to hysteria and also that the anaesthesia which is common in alcoholics is not a separate illness but a symptom of hysteria. However, he opposes the idea of setting up such a number of subspecies of hysteria (traumatic, alcoholic, due to plumbism, etc.); hysteria, he insists, is always the same, and merely provoked by a variety of incidental causes. In recent syphilis, too, the outbreak of hysterical symptoms has been observed.

IV. COURSE TAKEN BY HYSTERIA

Hysteria represents a constitutional anomaly rather than a circumscribed
[52] illness. As a rule, first signs of it are probably exhibited in early youth. In fact, hysterical illnesses even of troublesome severity are no rarity in children of between six and ten years. In boys and girls of intense hysterical disposition, the period before and after puberty brings about a first outbreak of the neurosis. In infantile hysteria the same symptoms are found as in adult neuroses. Stigmata, however, are as a rule rarer, and psychical changes, spasms, attacks and contractures are in the foreground. Hysterical children are very frequently precocious and highly gifted; in a number of cases, to be sure, the hysteria is merely a symptom of a deep-going degeneracy of the nervous system which is manifested in permanent moral perversion. As is well known, an early age, from fifteen onwards, is the period at which the hysterical neurosis most usually shows itself actively in females. This can happen either by an unbroken succession of comparatively slight disturbances (*chronic* hysteria) or by several severe outbreaks (*acute* hysteria) separated by free intervals lasting for years. The first years of a happy marriage interrupt the illness as a rule; when marital relations become cooler and repeated births have brought exhaustion, the neurosis reappears. After the age of forty in women the illness does not usually produce fresh phenomena; but the old symptoms may persist and strong provocations may intensify the illness even at an advanced age. Males at an immature age seem to be particularly susceptible to hysteria through trauma and intoxication. *Hysteria in males* gives the appearance of a severe illness; the symptoms it produces are as a rule obstinate; the illness in men, since it has the

greater significance of being an occupational interruption, is of greater practical importance. – There is something very characteristic about the course taken by the different hysterical symptoms (such as contractures, paralyses, etc.). In some cases the individual symptoms very rapidly disappear spontaneously and give place to others equally transitory; in other cases all the phenomena are dominated by great rigidity. Contractures and paralyses will often last for years and will then unexpectedly and suddenly pass off. In general, there is no limit to the curability of hysterical disorders, and it is characteristic for a disturbed function, after being interrupted for years, to be suddenly restored to its full extent. On the other hand, the development of hysterical disorders often calls for a sort of incubation, or rather for a period of latency, during which the provoking cause continues to operate in the unconscious.[1] Thus, a hysterical paralysis scarcely ever emerges immediately after a trauma; people involved in a railway accident, for instance, are all able to move after the trauma, they go home apparently unhurt, and it is only after [53] days or weeks that the phenomena are generated which lead to the assumption of a 'concussion of the spinal cord'. So, too, the recovery which suddenly sets in usually requires a period of several days for its development. In any case, it may be asserted that hysteria never, even in its most threatening manifestations, involves a serious risk to life. Moreover, complete intellectual [*Geistes*] clarity and a capacity even for unusual achievements is retained in the most protracted cases of hysteria.[2]

Hysteria may be combined with many other neurotic and organic nervous diseases, and such cases offer great difficulties to analysis.[3] The commonest combination is of hysteria with neurasthenia; this occurs either when people whose hysterical disposition is almost exhausted become neurasthenic, or when stressful influences[4] provoke both neuroses simultaneously. Unfortunately, the majority of physicians have not yet learnt to distinguish the two neuroses from each other. This combination is found most frequently in hysterical men. The male nervous system has as preponderant a disposition to neurasthenia as the female to hysteria. Moreover, the frequency of female hysteria too is overestimated; the majority of the women feared to be hysterical by physicians are strictly speaking merely neurasthenic. Furthermore, 'local

1 [This seems to be Freud's first published use of the term 'the unconscious'.]

2 [Freud often asserts this, in the face of Janet's contrary view (1894, 300). See, for instance, the cases of Frau Cäcilie M. and Frau Emmy von N. in *Studies on Hysteria* (1895*d*), *RSE*, **2**, 91–2.]

3 [Not of course in the sense of 'psychoanalysis'.]

4 ['*aufreibender Einwirkungen*.' Inexplicably translated as 'exasperating impressions' in the *SE*.]

hysteria' may accompany local illnesses of individual organs; a joint which is really fungal can become the seat of a hysterical arthralgia; a stomach with a catarrhal affection can give rise to hysterical vomiting, *globus hystericus* and anaesthesia or hyperaesthesia of the skin of the epigastrium. In these cases the organic illness becomes an incidental cause of the neurosis. Feverish illnesses usually interrupt the development of a hysterical neurosis; a hysterical hemianaesthesia will recede in fever.

V. TREATMENT OF THE NEUROSIS

This can scarcely be dealt with briefly. In the face of no other illness can the physician perform such miracles or remain so impotent. From the standpoint of treatment three tasks must be separated: the treatment of the hysterical disposition, of hysterical outbreaks (*acute hysteria*), and of individual hysterical symptoms (*local hysteria*). In treating the hysterical disposition a certain freedom of manoeuvre is open to the physician. The disposition cannot be done away with; but one can take prophylactic
[54] measures to see to it that physical exercises and hygiene are not pushed into the background by intellectual work; one can advise against overstraining the nervous system; one can treat anaemia or chlorosis, which seems to lend special support to the tendency to neurosis; lastly, one can discount the importance of slight hysterical symptoms. One must guard against exhibiting too clearly one's interest as a physician in slight hysterical symptoms and so encouraging them. Serious intellectual work, even if it is exacting, seldom brings on hysteria, though, on the other hand, that reproach may be levelled against education in the better classes of society, which strives towards the refinement of feeling and of sensibility. To that extent the methods of earlier generations of physicians (who treated hysterical manifestations in young people as naughtiness and weakness of will and threatened them with punishment) were not bad ones, though they were hardly based on correct views. In the treatment of neurosis in children, more can be achieved by authoritative prohibition than by any other method. This kind of treatment, to be sure, will meet with no success if it is applied to hysteria in adults or to severe cases. In the treatment of acute hysterias, in which the neurosis constantly produces new phenomena, the physician's task is a hard one: it is easy to make mistakes and successes are rare. The first condition for a successful intervention is as a rule a removal of the patient from his regular conditions and his isolation from the circle in which the outbreak

occurred. These measures are not only beneficial in themselves but also make possible a strict medical supervision and enable the physician to devote the close attention to the patient without which he will never achieve success in the treatment of hysteria. As a rule a hysterical man or woman is not the only neurotic member of the family circle. The alarm or tender concern of parents or relatives only increases the patient's excitement or his inclination, where there is a psychical change in him, to produce more intense symptoms. If, for instance, an attack has come on at a particular hour several times in succession, it will be expected by the patient's mother regularly at the same time; she will ask the child anxiously whether he is already feeling bad and so make it certain that the dreaded event will occur. Only in the rarest instances can one succeed in inducing relatives to look on at a child's hysterical attacks quite calmly and with apparent indifference; as a rule the family's place must be taken by a period in a medical establishment, and to this the relatives usually offer greater resistance than do the patients themselves. The patient's altered perceptions in the sanatorium, the physician's friendly and cheerful certainty and his conviction, which is soon transferred to [55]
the patient, that the neurosis is not dangerous and can be rapidly cured, the avoidance of all emotional excitement which might contribute to a hysterical outbreak, the application of every kind of strengthening remedy (massage, general faradization, hydrotherapy) – under all these influences the most severe acute hysterias, which have led to the patient's total physical and moral derangement, are found to give place to health in the course of a few months. In recent years the so-called 'rest cure' of Weir Mitchell (also known as Playfair's treatment) has gained a high reputation as a method of treating hysteria in institutions, and deservedly so. It consists in a combination of isolation in absolute quiet with a systematic application of massage and general faradization;[1] the attendance of a trained nurse is as essential as the constant influence of the physician. This treatment is of extraordinary value for hysteria, as a happy combination of '*traitement moral*' with an improvement in the patient's general nutritional state. It is not to be regarded, however, as something systematically complete in itself; the isolation, rather, and the physician's influence remain the principal agents, and, along with massage and electricity, the other therapeutic methods are not to be neglected. The best plan is, after four to eight weeks of rest in bed,

1 [Cf. Freud's review of Weir Mitchell's book on the treatment of neurasthenia and hysteria (p. 36 f. above). At a later date Freud recommended a combination of Weir Mitchell's rest cure with Breuer's cathartic treatment. Cf. *Studies on Hysteria* (1895*d*), *RSE*, **2**, 237 f.]

to apply *hydrotherapy* and *gymnastics* and to encourage plenty of movement. In the case of other neuroses, for instance of neurasthenia, the success of the treatment is far less certain: it rests merely on the value of excessive feeding, so far as this succeeds with a neurasthenic digestive tract, and of rest; in hysteria the success is often magical and permanent.

The treatment of individual hysterical symptoms offers no prospect of success so long as an acute hysteria subsists: symptoms that have been got rid of return or are replaced by new ones. Finally, both physician and patient grow weary. The position is different, however, if the hysterical symptoms represent a residue of an acute hysteria which has run its course, or if they appear in a chronic hysteria, owing to some special exciting cause, as localizations of the neurosis. To begin with, internal medication is to be disrecommended here and narcotic drugs are to be warned against. To prescribe a narcotic drug in an acute hysteria is nothing less than a serious technical mistake. In the case of local and resistant hysteria it may not always be possible to avoid internal medicaments; but
[56] their effect is untrustworthy. Sometimes it comes about with magical promptitude, sometimes not at all, and it seems to depend on the patient's autosuggestion or on his belief in its effectiveness. Apart from this we have a choice between initiating direct or indirect treatment of the hysterical ailment. The latter consists in neglecting the local complaint and in aiming at a general influence upon the nervous system, in the course of which we make use of an outdoor life, hydrotherapy, electricity (preferably by high-tension treatment), and improving the blood by arsenic and iron medication. We have further, with indirect treatment, to consider the removal of sources of stimulus if any of a physical nature exist. Thus, for instance, hysterical gastric spasms may have as their basis a slight gastric catarrh, while a reddened area in the larynx or a swelling of the turbinal may give rise to an unceasing *tussis hysterica*. Whether changes in the genitals really constitute so often the sources of stimulus for hysterical symptoms is in fact doubtful. Such cases must be more critically examined. Direct treatment consists in the removal of the psychical sources of stimulus for the hysterical symptoms, and is understandable if we look for the causes of hysteria in unconscious ideational life [*Vorstellungsleben*]. It consists in giving the patient under *hypnosis* a *suggestion* which contains the removal of the disorder in question. Thus, for instance, we cure a *tussis nervosa hysterica* by pressing on the larynx of the hypnotized patient and assuring him that the stimulus to coughing has been removed, or we cure a hysterical paralysis of the arm by compelling him under hypnosis to move the paralysed limb piece by piece. It

is even more effective if we adopt a method first practised by Josef Breuer in Vienna and lead the patient under hypnosis back to the psychical prehistory of the ailment and compel him to acknowledge the psychical occasion on which the disorder in question originated. This method of treatment is new, but it produces successful cures which cannot otherwise be achieved. It is the method most appropriate to hysteria, because it precisely imitates the mechanism of the origin and passing of these hysterical disorders. For many hysterical symptoms, which have resisted every treatment, vanish spontaneously under the influence of a sufficient psychical motive [*Motiv*][T] (for instance, a paralysis of the right hand will vanish if in a dispute the patient feels an impulse to box his opponent's ear) or under the influence of some moral excitement or of a fright or of an expectation (e.g. at a place of pilgrimage) or, lastly, when there is an upheaval of the excitations in the nervous system after an attack of convulsions. The direct psychical treatment of hysterical symptoms will be considered the best some day, when the understanding of suggestion has [57]
penetrated more deeply into medical circles (Bernheim – Nancy). – It cannot at present be decided with certainty how far psychical influence plays a part in certain other apparently physical treatments. Thus, for instance, contractures can be cured if one can succeed in bringing about a *transfert* by means of a magnet. If there are repeated *transferts*, the contracture grows weaker and eventually disappears.[1]

VI. RÉSUMÉ

By way of summary we may say that hysteria is an anomaly of the nervous system which is based on a different distribution of excitations, probably accompanied by a surplus of stimuli in the organ of the mind [*Seelenorgan*][T]. Its symptomatology shows that this surplus is distrib- *Seele*
uted by means of conscious or unconscious ideas. Anything that alters the distribution of the excitations in the nervous system may cure hysterical disorders: such effects are in part of a physical and in part of a directly psychical nature.

1 [It should be remarked, however, that Andersson (1962, 89 ff.) has argued that the account given here of Breuer's therapeutic technique relates only to a specially efficient use of suggestion and does not cover what was to become the essential discovery of abreaction.]

APPENDIX

HYSTERO-EPILEPSY[1]

HYSTERO-EPILEPSY (French, *hystéroépilepsie*; English, *hystero-epilepsy*; Italian, *isteroepilessia*). [58]

In hystero-epilepsy attacks of general convulsions are observed, as in epilepsy.[2] As precursors there appear: a feeling of suffocation, difficulty in swallowing, headache and stomach-ache, vertigo and certain peculiar dragging sensations in the extremities. The patients fall down with a loud cry and are seized with convulsions, they foam at the mouth and their features are distorted. The convulsions are of a tonic nature to start with, but later clonic. Usually, however, the attack does not come on as suddenly as it does in epilepsy. For a short time the patients try to fight against the convulsions, to save themselves from serious injuries as they fall down and to avoid dangerous situations. An epileptic will even fall into the fire, but that does not occur with hysterics. While the former is pale at the beginning of the attack and later cyanotic, a hysteric's face retains more or less its normal colour. Injuries to the tongue from biting are rare in hysteria. In hystero-epileptic attacks complete opisthotonus often occurs, but not usually in epilepsy. During the attacks consciousness does not disappear completely except in the most severe cases. After [59]

1 [*Hysteroepilepsie*. – As explained above, p. 41 *n*., this article also appeared, unsigned, in Villaret (1888, 1891). It was reprinted in *GW*, **Nachtr.**, 69, and *SFG*, **2**, 261–2. The translation (by James Strachey) first appeared in *SE*, **1**, 58–9.]

2 Charcot used in earlier days to describe as hystero-epilepsy the severe cases of hysteria which included in their attacks an *epileptoid phase*. Since then he has abandoned this name, which leads to endless misunderstandings, and he now describes such cases as '*grande hystérie*' (p. 44 above). Accordingly, no special value is to be attached to the term 'hystero-epilepsy', and one must particularly guard against the view that a special disease combining the characteristics of hysteria and epilepsy is to be understood by it. There are people who are hysterical *and* epileptic; but in that case the two conditions exist side by side, one illness as a complication of the other, without any mutual modification; and the attacks of these patients are on each occasion *either* hysterical *or* epileptic. – [The gist of this footnote was repeated by Freud in a footnote which he added to his translation of Charcot's *Leçons du mardi* published soon after this (1892–94*a*). It can be found below, pp. 169–70. – Freud discussed the distinction between hysterical and epileptic fits later, in his paper on hysterical attacks (1909*a*), *RSE*, **9**, 205, but at very much greater length in his paper on Dostoevsky (1928*b*), ibid., **21**, 167 ff.]

the attack a hysteric usually recovers at once; no inclination to sleep and no feebleness remain, as they do with epileptics. On the other hand, visions of rats, mice and snakes afterwards are not uncommon, and similarly auditory hallucinations. Besides these attacks, all the symptoms of hysteria are found in these patients.

PAPERS ON HYPNOTISM AND SUGGESTION

(1888–92)

PAPERS ON HYPNOTISM AND SUGGESTION

EDITORS' INTRODUCTION

After Freud's return to Vienna from Paris in 1886, he devoted much of his attention for [63]
some years to a study of hypnotism and suggestion. Though, of course, the subject crops up at many points (for instance, in *Studies on Hysteria* and the obituary of Charcot), writings from this period dealing with it *directly* seemed for many years to be either non-existent or out of reach, except for the Preface to the translation of Bernheim's *De la suggestion* (1888–89*a*) and the paper 'A Case of Successful Treatment by Hypnotism' (1892–93*a*). At the time of the first publication of this volume of the *SE* (1966) we seemed able to insert three fairly long works between these two. In the first place Strachey exhumed the review of Forel's book on hypnotism (1889*a*), which had at that time never been reprinted. The other two were newcomers in different ways.

Of these the first is actually an old acquaintance: the article bearing the title 'Psychical (or Mental) Treatment' (1905*b*), which appeared in *SE*, 7. That volume of the *SE* was published in 1953. By 1966 Strachey thought, on the basis of research by Saul Rosenzweig, that he had misdated the article and that it had actually been published in 1890. He therefore recommended that it be relocated to this volume, after the review of Forel. Subsequent research by Gerhard Fichtner revealed that Rosenzweig had in fact erred. The article was composed circa 1894–95 and published in 1905, not before. It therefore does not belong here after all. The whole issue is more fully discussed in the Editors' Note to the article, in Volume 7, where it now remains.[1]

The other newcomer in 1966 was a complete revelation. It was an article on hypnosis [64]
contributed by Freud to a medical handbook, *Therapeutisches Lexikon*, edited by A. Bum, and first published in 1891. (It had a second edition in 1893 and a third in 1900.) No trace of the existence of this article was to be found anywhere until its discovery by Paul F. Cranefield, then editor of the *Bulletin* of the New York Academy of Medicine.

For the *RSE* two further newcomers may be introduced. The first is Freud's (1888*u*) previously forgotten review of Obersteiner's *Hypnotismus* – discovered by the late Oswald Kästle – which now opens this series of papers. The second is a report of a lecture delivered by Freud in 1892 on the subject of hypnosis and suggestion. Since the report bears every mark of being an accurate rendition of the lecture, and in view of the paucity of publications from this period representing Freud's views on the topic, it was thought worthwhile to include it in the *RSE*. Freud's only other possibly relevant publication, his review of Berkhan's 'Deaf-Mutism', which does not touch at all on psychological matters, appears earlier in this volume (p. 37 above).

1 Incidentally, there is a reference to *Die Gesundheit* in a letter of Freud's to Oskar Pfister on June 17, 1910, in which he remarked, evidently in connection with the question of the 'sexual enlightenment' of children: 'the book which I put in my children's hands is a popular medical work, *Die Gesundheit*, to which I myself contributed' (Freud, 1963*a*).

Freud's clinical experience with hypnotism can be traced in some detail. In his *Autobiographical Study* (1925*d*), he reports that while he was still a student he attended a public exhibition given by Hansen[1] the 'magnetist' and was convinced of the genuineness of the phenomena of hypnosis (*RSE*, **20**, 13). In his early twenties, moreover, Freud became aware that his future collaborator Breuer (a man almost fifteen years his senior) was sometimes using hypnotism for therapeutic purposes. At that period, however, many high medical authorities in Vienna still exhibited alarmist or sceptical views on the subject. (See, for instance, the remarks of Freud's old teacher, Meynert, quoted in the review of Forel, p. 100 ff. below.) And it was only when, at the age of thirty, he arrived at Charcot's clinic in Paris that he found hypnotic suggestion in recognized and daily use. The profound effect which this produced on him is shown in the report he made on his return from Paris in 1886 (1956*a*), p. 12 f. above, as well as in many later passages.[2] After settling in Vienna as a nerve specialist, he made attempts at using various procedures, such as electrotherapy, hydrotherapy and rest cures, for treating the neuroses, but fell back in the end on hypnotism. 'During the last few weeks,' he wrote to Fliess on December 28, 1887, 'I have taken up hypnosis and have had all sorts of small but remarkable successes.' In the same letter he reported that he was already under contract to translate Bernheim's book on suggestion. But this pre-
[65] cipitancy was not the result of enthusiasm, for, in a letter to Fliess of the following August 29 which probably accompanied a copy of his Preface (itself dated 'August, 1888') to Bernheim's book, he wrote that he only undertook the translation most unwillingly and for merely practical reasons (Freud, 1950*a*, Letter 5). Hypnotic *suggestion* was no doubt his immediate concern; but he once again reports in the *Autobiographical Study* (1925*d*), *RSE*, **20**, 16, that 'from the very first I made use of hypnosis in *another* manner, apart from hypnotic suggestion'. By this he of course meant Breuer's method of using hypnotism for tracing back the origin of symptoms.[3] There is some doubt as to exactly when he started on this new procedure: but he certainly used it in the case of Frau Emmy von N., whom he began treating in May, 1889, or possibly a year earlier. (See footnote 1 on p. 67 and footnote 2 on p. 68 below.) Thereafter he became more and more involved in Breuer's cathartic procedure.

In the meantime Freud's interest in hypnotic suggestion continued. The Bernheim translation seems to have finished appearing early in 1889. By then Freud was already in contact with August Forel, the well-known Swiss psychiatrist, whose book on hypnotism he reviewed in two instalments in July and November, 1889 (p. 99 below); and it was on Forel's introduction that (between the two instalments) he paid a visit of some weeks to Bernheim and Liébeault at Nancy.[4] His motive for doing so was,

1 Carl Hansen (1833–97), the Danish mesmerist, whose popular demonstrations, given not only in Denmark but also throughout a great part of Europe, did much to reawaken interest in hypnosis. Disapproval from official circles led in the 1880s to his being forbidden by the police from appearing publicly, both in Stockholm and Vienna. He continued to give private séances, however, with undiminished success.

2 Very soon after his return to Vienna in April, 1886, he gave two lectures on hypnotism – before the Vienna Physiological Club on May 11 and before the Psychiatric Society on May 27. (Cf. Jones, 1953, 252.)

3 This was already described in the Villaret article of 1888 (p. 58 f. above); but cf. the footnote on p. 59 above.

4 Freud gave more than one account of this visit, e.g. in his *Autobiographical Study*, in his *Introductory Lectures* (1916–17*a*), *RSE*, **15**, 90 f., and in 'Some Elementary Lessons in Psycho-Analysis'

he tells us (*RSE*, **20**, 14), the idea of perfecting his hypnotic technique. For the fact is that Freud did not regard himself as a great adept in the art of hypnotizing, or else he was more honest than many people in recognizing the limitations of the procedure.[1] As early as 1891, when he published the contribution to Bum's medical [66]
dictionary which can be found below, he was evidently aware of these difficulties and was moreover beginning to feel irritated by them (p. 122 f. below). His irritation was expressed again soon afterwards, in a footnote to his translation (1892–94*a*) of Charcot's *Leçons du mardi* (p. 168) and still more freely in a passage in the case history of Miss Lucy R. in *Studies on Hysteria* (1895*d*), *RSE*, **2**, 95–7. He summed up the position many years later in his *Five Lectures* (1910*a*), ibid., **11**, 23: 'But I soon came to dislike hypnosis . . . When I found that, in spite of all my efforts, I could not succeed in bringing more than a fraction of my patients into a hypnotic state, I determined to give up hypnosis . . .' But the moment for this had not yet arrived. He continued to make use of hypnosis not only as part of the cathartic method but also for straightforward suggestion, and at the end of 1892 he published a detailed account of a particularly successful case of this kind. (See p. 145 below.) In the same year, moreover, he produced a translation of a second book of Bernheim's (1892*a*), though this time without an introduction. The lecture he gave on the topic before the Vienna 'Medizinischer Club' (p. 129) dates to the same year. Before long, however, he devised a scheme by which he could produce the effects of suggestion without the need for putting the patient into a state of hypnosis. The first plan was to substitute what he called a state of 'concentration' for hypnotic sleep (*Studies on Hysteria*, 1895*d*; *RSE*, **2**, 95–7). He next developed the 'pressure technique' (ibid., 97–8, 129, 136 f. and 241 ff.): by simply pressing on the patient's forehead with his hands he was able to elicit the information he required.[2] It is not clear whether he first employed this method in the case of Miss Lucy R. or of Fräulein Elisabeth von R., both of whose treatments began at the end of 1892. This method was of course of use only in cathartic and not in suggestive treatment.

Precise dates for Freud's abandonment of these various procedures are not obtainable. In a lecture delivered at the end of 1904 (1905*a*), he declared (ibid., **7**, 270): 'Now I have not used hypnosis for therapeutic purposes for some eight years (except for a few special experiments)' – since about 1896, therefore. This may perhaps also cover the end of the 'pressure' technique, for he made no mention of any such contact with

(1940*b* [1938]), *RSE*, **23**, 266 f. – Ambroise-Antoine Liébeault (1823–1904), medical practitioner at Nancy, was founder of the therapeutics of suggestion and its first methodical user. He was a teacher and later collaborator of Bernheim. Freud acknowledges his debt to Liébeault's theory of sleep in *The Interpretation of Dreams* (1900*a*), ibid., **5**, 510 *n.*, where he states that the revival in modern times of research into hypnotism is due to Liébeault.

1 His doubts about the efficacy of suggestion must have begun early. In his *Autobiographical Study* (1925*d*), ibid., **20**, 14–15, he tells us that he persuaded a patient with whom he had failed to produce deep hypnosis to join him in Nancy. But Bernheim too was unsuccessful with her and confessed to him that his great successes were achieved only with his hospital patients and not in his private practice. The identity of this patient is unknown, though it has been suggested, not very convincingly, that she may actually have been Frau Emmy von N. However that may be, Freud himself (in a letter written some twenty years later) specifically attributed his realization of the inefficiency of hypnotic treatment to his experience with Frau Emmy von N. Cf. also footnote 2, p. 68 below, and Andersson (1979).

2 A further discussion of this technique can be found in an Editors' footnote in *RSE*, **2**, 98 *n.* Cf. also the three-part lecture 'On Hysteria' (Freud, 1895*g*), ibid., **2**, 291 ff.

[67] the patient in the account of his procedure at the beginning of *The Interpretation of Dreams* (1900*a* [1899]), *RSE*, **4**, 90, though in that passage he still recommended keeping the eyes closed. But in a contribution to Löwenfeld's book on obsessions in which he described his technique (1904*a*), he explicitly wrote: 'He [Freud] does not even ask them to close their eyes, and avoids touching them in any way, as well as any other procedure which might be reminiscent of hypnosis' (ibid., **7**, 224). Actually, a trace of hypnotism still remained to the very end – the 'ceremonial which concerns the position in which the treatment is carried out . . . it is the remnant of the hypnotic method out of which psychoanalysis was evolved', and which Freud thought deserved to be maintained for many reasons ('On Beginning the Treatment', 1913*c*; ibid., **12**, 130–1). The period during which Freud made any effective use of hypnosis is therefore covered at the outside by the years between 1886 and 1896.[1]

Freud's interest in the *theory* of hypnotism and suggestion naturally lasted longer. Here there was controversy along lines which may be crudely described as 'Charcot versus Bernheim' – between the view of the Salpêtrière that suggestion was merely a mild form of hypnosis and the view of the Nancy school that hypnosis was merely a product of suggestion. It is possible to detect signs of oscillation in Freud's attitude to the debate. In the letter to Fliess of August 29, 1888, from which we have already quoted and which he sent immediately after writing his Preface to Bernheim's book, he wrote: 'I do not share Bernheim's views, which seem to me one-sided, and in my preface I have tried to defend Charcot's point of view.'[2] The lines along which Freud did this will be gathered from the Preface itself (p. 84 ff. below). This was, of course,
[68] before his visit to Nancy, which probably influenced him greatly, for, not long afterwards, in his obituary of Charcot (1893*f*), *NSW*, **4**, he wrote critically of 'the exclusively nosographical approach adopted at the school of the Salpêtrière' to hypnotic phenomena: 'the restriction of the study of hypnosis to hysterical patients, the differentiation between major and minor hypnotism, the hypothesis of three stages of "major hypnosis", and their characterization by somatic phenomena – all this sank in the estimation of Charcot's contemporaries when Liébeault's pupil, Bernheim, set about constructing the theory of hypnotism on a more comprehensive psychological foundation and making suggestion the central point of hypnosis.' (*RSE*, **3**, 21.) In several later passages Freud insisted, however, on the vagueness of the term 'suggestion' and on the fact that Bernheim himself was unable to explain the mechanism of the process: for instance, already in the Forel review (1889*a*), p. 109 below, and again in the 'Little Hans' case history (1909*b*), *RSE*, **10**, 79, and in the *Introductory Lectures* (1916–17*a*), ibid., **16**, 394. He returned to this once more in

1 1896 was the year in which the second edition of Freud's first Bernheim translation was published. As can be seen below (p. 93), he made the most drastic cuts in the volume (particularly in the clinical sections) and entirely suppressed the elaborate introduction he had written for the first edition. This may well have been an expression of his increasing impatience with the whole method of treatment.

2 It is a little difficult to bring into complete harmony with this a statement by Freud in *Studies on Hysteria* (*RSE*, **2**, 89): 'It was while I was studying Frau von N.'s abulias that I began for the first time to have grave doubts about the validity of Bernheim's assertion, "*tout est dans la suggestion*".' Frau von N.'s analysis seems to have begun a year later than this letter to Fliess, in May, 1889 – though the date is not quite certain. See Appendix A to *Studies on Hysteria*, ibid., **2**, 309 ff., as well as Andersson (1979) and Ellenberger (1977).

Group Psychology (1921*c*), *RSE*, **18**, 83 f., a work in which there are a number of discussions both of suggestion and of hypnosis. And here in a footnote (ibid., 119 *n*.) he definitely withdrew from his earlier inclination to support Bernheim's views: 'It seems to me worth emphasizing the fact that the discussions in this section have induced us to give up Bernheim's conception of hypnosis and go back to the naive earlier one. According to Bernheim all hypnotic phenomena are to be traced to the factor of suggestion, which is not itself capable of further explanation. We have come to the conclusion that suggestion is a partial manifestation of the state of hypnosis, and that hypnosis is solidly founded upon a predisposition which has survived in the unconscious from the primal history of the human family.' The even balance of Freud's views on this controversy was brought out in a phrase in a letter of his to A. A. Roback many years later, on February 20, 1930: 'In the question of hypnosis I *did* take sides against Charcot, though not wholly with Bernheim' (Freud, 1960*a*, 391).

Also of interest regarding the theory of hypnotism are the opportunities it afforded Freud to begin grappling with the mind–body problem and the related notion of unconscious mental processes. Some of his earliest ideas on those fundamental issues appear in this series of papers. These are not infrequently linked with the question of the relationship between consciousness and cortical functioning, and between cortex and subcortex, especially insofar as they related to the views of Freud's erstwhile teacher, the highly esteemed Theodor Meynert.

In spite of his early abandonment of hypnosis as a therapeutic procedure, Freud never hesitated throughout his life to express his sense of gratitude to it. 'We psychoanalysts', he declared in the *Introductory Lectures* (1916–17*a*), *RSE*, **16**, 408, 'may claim to be its legitimate heirs and we do not forget how much encouragement and theoretical clarification we owe to it.' And he gave a more specific explanation of this in one of his technical papers (1914*g*): 'We must still be grateful to the old hypnotic technique for having brought before us single psychical processes of analysis in an [69]
isolated or schematic form. Only this could have given us the courage ourselves to create more complicated situations in the analytic treatment and to keep them clear before us.' (Ibid., **12**, 146.)

REVIEW OF OBERSTEINER'S *HYPNOTISM*

(1888)

EDITORS' NOTE

REVIEW OF H. OBERSTEINER'S *DER HYPNOTISMUS*

GERMAN EDITIONS

1888 *Zbl. Physiol.*, **1** (23), 632–3. (February 4.)
1987 *GW*, **Nachtr.**, 105–6.
2015 *SFG*, **2**, 313–14.

ENGLISH TRANSLATION

1989 *Int. J. Psycho-Anal.*, **70** (3), 402. (Tr. Mark Solms.)

The present translation is a slightly revised reprint of the one published in 1989.

Obersteiner's monograph, the full title of which is *Der Hypnotismus mit besonderer Berücksichtigung seiner klinischen und forensischen Bedeutung* ('Hypnotism with Particular Consideration of its Clinical and Forensic Significance'), was published in 1887 in the series *Klinische Zeit- und Streitfragen*, **1** (2), 49–80. Vienna: Verlag Braumüller.

Heinrich Obersteiner (1847–1922) was, like Freud, a neuroanatomist as well as a practising neurologist, and later became head of the famous Institute of Neurology in Vienna. Freud knew Obersteiner personally at a time when the latter already had considerable experience with hypnosis, and he may have been one of the major pre-Charcot influences on the young Freud. (Cf. Jones, 1953.)

Apart from the present review, Freud also wrote a review of a neuroanatomical textbook by Obersteiner (Freud, 1887*e*), *NSW*, **1**, and Obersteiner, in turn, wrote two reviews of works by Freud (Obersteiner, 1882, 1888). Obersteiner publicly supported Freud's controversial views on cocaine (Obersteiner, 1884, 11; incorrectly cited as 1885 by Jones, 1953, 103). He also endorsed Breuer and Freud's early conceptualizations of hysteria and their therapeutic innovations. For a comprehensive discussion of their relationship, see Fichtner & Hirschmüller (1988*a*, *b*).

The chief interest of the present review is that, together with his review of Berkhan's 'Deaf-Mutism' (p. 37 above), it represents one of Freud's first published references to the subject of hypnotism. Written shortly after his return from Paris, when he was still particularly enthusiastic about hypnosis (cf. p. 5 ff.), it accordingly expresses overwhelmingly positive views about its clinical and scientific (and one might almost say ontological) significance.

REVIEW OF OBERSTEINER'S *HYPNOTISM*

This 80-page[1] text sets itself the task of characterizing as succinctly as possible the standpoint reached by the doctrine of hypnotism through the investigations of recent years, and it seeks thereby to show the physician how necessary it is for him to make himself more familiar with this subject. On the basis of his rich knowledge of the literature, and his own experience, Obersteiner deals with the method of inducing hypnosis, with the manifestations of hypnosis in the sensory and motor areas, the vegetative sphere, and in psychical phenomena, as well as with the facts and problems connected with 'suggestion', and further, with the therapeutic application of hypnosis, which seems destined to play a substantial role in the therapy of the neuroses, and with the forensic significance of hypnotic states. What must be emphasized is the scientifically correct standpoint of the author, who carefully avoids rejecting as impossible or fallacious anything which goes beyond the realm of his own experience, and who consistently differentiates between a seemingly miraculous factual assertion and its [in]explicability by our current physiological notions. Regarding the influence exerted on the nervous system by magnets, Obersteiner takes the view that a 'magnetic sense' is to be attributed to man, the sensations of which normally remain below the threshold [of consciousness], but which rise above it under pathological conditions (hypnosis, hysteria). It seems to this reviewer that Obersteiner makes an inappropriate comment on the famous experiment of Babinski [1886][2] with Charcot, where a suggestion was transferred from one hypnotized person to another by means of a magnet. If one is to assume that the magnet can possibly have an effect upon a person, then it should not appear strange if this person in turn influences a second – just as a magnetized piece of soft iron acquires the property of attracting a second. To be sure, this analogy does not

1 [This is an error; the monograph was actually 32 pages long, but spanned pp. 49–80 of the volume in which it was bound.]

2 [See footnote 1, p. 161 below.]

diminish the incredibility of the fact that one nervous system can influence another nervous system by means other than the sensory perceptions known to us. One must just concede that a confirmation of these experiments would add something new, hitherto unrecognized, to our *Weltanschauung*, and expand the borders of the personality as it were.[1]

1 [Freud (1904*d*) later took the view that there 'can naturally be no question of the magnet having an actual effect upon the person' (*RSE*, **7**, 317). However, he always remained open to the possibility that one nervous system can influence another nervous system by means other than the sensory perceptions known to us (see Freud, 1933*a*; ibid., **22**, 49).]

PREFACE TO THE TRANSLATION OF BERNHEIM'S *SUGGESTION*

(1888 [1888–89])

EDITORS' NOTE

PREFACE TO THE TRANSLATION OF BERNHEIM'S *DE LA SUGGESTION*

GERMAN EDITIONS

1888 In H. Bernheim, *Die Suggestion und ihre Heilwirkung* ('Suggestion and its Therapeutic Effects'), Leipzig and Vienna: Deuticke, iii–xii. (1896, 2nd ed.) [73]
1981 *Psyche*, **35** (5), 462–73.
1987 *GW*, **Nachtr.**, 109–20.
2015 *SFG*, **2**, 319–32.

ENGLISH TRANSLATIONS

1946 *Int. J. Psycho-Anal.*, **27** (1–2), 59–64. (Under the title 'Hypnotism and Suggestion'.) (Tr. James Strachey.)
1950 *CP*, **5**, 11–24. (Revision of above.)
1966 *SE*, **1**, 75–85. (Considerably corrected version of the 1950 translation.)

The present translation is a further revision of the *SE* version.

The full French title of Bernheim's book was *De la suggestion et de ses applications à la thérapeutique* (Paris: 1886; 2nd ed. 1887). An advance extract from Freud's translation appeared in the *Wiener med. Wochenschrift*, **38** (26), 898–900, on June 30, 1888, under the title 'Hypnose durch Suggestion' ('Hypnosis by Suggestion'); and the whole of Freud's Preface, except for its first two paragraphs, was published in the *Wien. med. Bl.*, **11** (38), 1189–93, and (39), 1226–8, on September 20 and 27, 1888, under the title 'Hypnotismus und Suggestion'. Though the title page of the volume bears the date '1888', its publication was not in fact completed till 1889, as is shown by a 'Translator's Postscript' appearing on the last page:

> In consequence of personal circumstances affecting the translator, the appearance of the second part [the book is in two parts] has been postponed for some months beyond the promised date. Even now I should probably not have reached the end had not my respected friend Dr Otto von Springer had the great kindness to take over the translation of all the case histories in the second part, for which I owe him my best thanks.
>
> Vienna, January, 1889.

Nothing is known of what these 'personal circumstances' were – whether, for instance, they were the same as the 'accidental and personal reasons' which, at about the same period, held back Freud's completion of his French paper on the organic and hysterical paralyses (1893*c*), p. 187 below. Freud added only a very few and very brief translator's notes to the text of this volume, and these were mostly references
[74] to German editions of works mentioned by Bernheim. The only one that calls for notice is quoted on p. 90 below.

In his *Autobiographical Study*, Freud shows some confusion over the date of publication of the present work. After describing his visit to Bernheim at Nancy, which took place in the summer of 1889, he ends up: 'I had many stimulating conversations with him, and undertook to translate into German his two works upon suggestion and its therapeutic effects' (*RSE*, **20**, 15). Actually, as we have seen, this book was already published before the visit took place. The second book of Bernheim's to be translated by Freud – *Hypnotisme, suggestion, psychothérapie: études nouvelles* – was not published in French till two years later (Paris: 1891). Freud's translation appeared the following year under the title *Neue Studien über Hypnotismus, Suggestion und Psychotherapie* (Leipzig and Vienna: Deuticke). This volume contained neither an introduction nor notes by the translator. The book was, however, warmly praised by Freud in the second half of his lecture 'On Hypnosis and Suggestion' (1892*b*), p. 138 below.

In 1896, a second edition of the first of the two volumes was published. But this, as we shall see, was entirely revised, under the supervision of Dr Max Kahane, an early adherent of Freud's, who also took over the second volume of the translation of Charcot's *Leçons du mardi* (see p. 160 *n*. 2 below). In this second edition, the present introduction was – not, as has been said, shortened – but entirely removed, and replaced by the brief Preface which we reproduce in an Appendix below (p. 93).

PREFACE TO THE TRANSLATION OF BERNHEIM'S *SUGGESTION*

This book has already received warm commendation from Professor Forel of Zürich,[1] and it is to be hoped that its readers will discover in it all the qualities which have led the translator to present it in German. They will find that the work of Dr Bernheim of Nancy provides an admirable introduction to the study of hypnotism (a subject which can no longer be neglected by physicians), that it is in many respects stimulating and in some positively illuminating, and that it is well calculated to destroy the belief that the problem of hypnosis is still surrounded, as Meynert asserts, by a 'halo of absurdity'.[2] [75]

The achievement of Bernheim (and of his colleagues at Nancy who are working along the same lines) consists precisely in stripping the manifestations of hypnotism of their strangeness by linking them up with familiar phenomena of normal psychological life and of sleep. The principal value of this book seems to me to lie in the proof it gives of the relations which link hypnotic phenomena with ordinary processes of waking and sleeping, and in its bringing to light the psychological laws that apply to both classes of events. In this way the problem of hypnosis is carried over completely into the sphere of psychology, and 'suggestion' is established as the nucleus of hypnotism and the key to its understanding. Moreover, in the last chapters the importance of suggestion is traced in fields other than that of hypnosis. In the second part of the book convincing evidence is offered that the use of hypnotic suggestion provides the physician with a powerful therapeutic method, which seems indeed to be the most suitable for combating certain nervous disorders and the most appropriate to their mechanism. This lends the volume a quite unusual practical importance. And its insistence upon the fact that both hypnosis and hypnotic suggestion can be applied, not only to hysterical and to seriously neuropathic patients, but also to the majority of healthy people, is

1 [See Freud (1889*a*), p. 99 ff. below.]

2 [Meynert (1888*a*, 718).]

calculated to extend the interest of physicians in this therapeutic method beyond the narrow circle of neuropathologists.[1]

The subject of hypnotism has had a most unfavourable reception among the leaders of German medical science (apart from such few exceptions as Krafft-Ebing, Forel, etc.). Yet, in spite of this, one may
[76] venture to express a wish that German physicians may turn their attention to this problem and to this therapeutic procedure, since it remains true that in scientific matters it is always experience, and never authority without experience, that gives the final verdict, whether in favour or against. Indeed, the objections which we have hitherto heard in Germany against the study and use of hypnosis deserve attention only on account of the names of their authors, and Professor Forel has had little trouble in refuting a whole crowd of those objections in a short essay [1889*a*].[2]

Some ten years ago the prevalent view in Germany was still one which doubted the reality of hypnotic phenomena and sought to explain the accounts given of them as due to a combination of credulity on the part of the observers and of simulation on the part of the subjects of the
Person experiments [*Versuchspersonen*][T]. This position is today no longer tenable, thanks to the works of Heidenhain[3] and Charcot, to name only the greatest of those who have lent their unimpeachable support to the reality of hypnotism. Even the most violent opponents of hypnotism have become aware of this, and consequently their writings, though they still betray a clear inclination to deny the reality of hypnosis, habitually also include attempts at explaining it and thus in fact recognize the existence of these phenomena.

Another line of argument hostile to hypnosis rejects it as being dangerous to the mental health of the subject and labels it as 'an experimentally produced psychosis'.[4] Evidence that hypnosis leads to injurious results in a few cases would no more decide against its general usefulness than, for instance, does the occurrence of isolated instances of death under chloroform narcosis forbid the use of chloroform for the purposes of surgical anaesthesia. It is a very remarkable fact, however, that this analogy cannot be carried any further. The largest number of accidents in chloroform narcosis are experienced by the surgeons who carry out the largest number of operations. But the majority of reports of the

1 [Cf. footnote 3, p. 5 above.]

2 [Later expanded into the book the review of which by Freud is printed below (p. 99 ff.).]

3 [Rudolf Peter Heinrich Heidenhain (1834–97) was Professor of Physiology and Histology at Breslau University from 1859.]

4 [Cf. Meynert (1888*b*) who described hypnosis as 'experimentally produced insanity'.]

injurious effects of hypnosis are derived from observers who have worked very little with hypnosis, whereas all those workers who have had a large amount of hypnotic experience are united in their belief in the harmlessness of the procedure. In order, therefore, to avoid any injurious effects in hypnosis, all that is probably necessary is to carry out the procedure with care, with a sufficiently sure touch and upon correctly selected cases. It must be added that there is little to be gained by [77]
calling suggestions 'obsessional ideas' ['*Zwangsvorstellungen*'][T] and hypnosis 'an experimental psychosis'. It seems likely that more light will be thrown on obsessional ideas by comparing them with suggestions than the other way round. And anyone who is scared by the abusive term 'psychosis' may well ask himself whether our natural sleep has any less claim to that description – if, indeed, there is anything at all to be gained from transporting technical names out of their proper spheres. No, the cause of hypnotism is in no danger from this quarter. And as soon as a large enough number of doctors are in a position to report observations of the kind that are to be found in the second part of Bernheim's book, it will become an established fact that hypnosis is a harmless condition and that to induce it is a procedure 'worthy' of a physician.

This book also discusses another question, which at the present time divides the supporters of hypnotism into two opposing camps. One party, whose opinions are voiced by Dr Bernheim in these pages, maintains that all the phenomena of hypnotism have the same origin: they arise, that is, from a suggestion, a conscious idea [*Vorstellung*][T], which has been introduced into the brain of the hypnotized person by an external influence and has been accepted by him as though it had arisen spontaneously. On this view all hypnotic manifestations would be psychical phenomena, effects of suggestions. The other party, on the contrary, stands by the view that the mechanism of some at least of the manifestations of hypnotism is based upon physiological changes – that is, upon displacements [*Verschiebungen*][T] of excitability [*Erregbarkeit*][T] *Erregung*
in the nervous system, occurring without the participation of those parts of it which operate with consciousness; they speak, therefore, of the physical or physiological phenomena of hypnosis.

The principal subject of this dispute is '*grand hypnotisme*' ['major hypnotism'] – the phenomena described by Charcot in the case of hypnotized hysterical patients. Unlike normal hypnotized subjects, these hysterical patients are said to exhibit three stages of hypnosis, each of which is distinguished by special physical signs of a most remarkable

kind (such as enormous neuromuscular hyperexcitability, somnambulistic contractures, etc.).[1] It will easily be understood what an important bearing, in connection with this region of facts, the difference of opinion [*Auffassung*][T] that has just been indicated must have. If the supporters
[78] of the suggestion theory are right, all the observations made at the Salpêtrière are worthless; indeed, they become errors in observation. The hypnosis of hysterical patients would have no characteristics of its own; but every physician would be free to produce any symptomatology that he liked in the patients he hypnotized. We should not learn from the study of major hypnotism what alterations in excitability succeed one another in the nervous system of hysterical patients in response to certain kinds of intervention; we should merely learn what intentions Charcot suggested (in a manner of which he himself was unconscious) to the subjects of his experiments – a thing entirely irrelevant to our understanding alike of hypnosis and of hysteria.

It is easy to see the further implications of this view and what a convenient explanation it can promise of the symptomatology of hysteria in general. If suggestion by the physician has falsified the phenomena of hysterical hypnosis, it is quite possible that it may also have interfered with the observation of the rest of hysterical symptomatology: it may have laid down laws governing hysterical attacks, paralyses, contractures, etc., which are only connected with the neurosis through suggestion and which consequently lose their validity as soon as another physician in another place makes an examination of hysterical patients. This inference follows quite logically, and has in fact already been drawn. Hückel (1888) expresses his conviction that the first '*transfert*' (the transferring [*Übertragung*][T] of sensibility from a part of the body to the corresponding part on the other side) made by a hysteric was suggested to her on some particular historical occasion and that since then physicians have continued constantly producing this professedly physiological symptom afresh by suggestion.

I am convinced that this view [*Auffassung*] will be most welcome to those who feel an inclination – and it is still the predominant one in Germany today – to overlook the fact that hysterical phenomena are governed by laws. Here we should have a splendid example of how neglect of the psychical factor of suggestion has misled a great observer into the artificial and false creation of a clinical type as a result of the capriciousness and easy malleability of a neurosis.

1 [Some account of these three stages of major hypnosis is given by Charcot in Lecture XXII of the volume translated by Freud shortly before this (Freud, 1886*f*, 275 ff.).]

Nevertheless, there is no difficulty in proving piece by piece the objectivity of the symptomatology of hysteria. Bernheim's criticisms may be fully justified in regard to investigations such as those of Binet & Féré;[1] and in any case those criticisms will show their importance in the fact that in every future investigation of hysteria and hypnotism the need for excluding the element of suggestion will be more consciously kept in view. But the principal points of the symptomatology of hysteria are safe [79] from the suspicion of having originated from suggestion by a physician. Reports coming from past times and from distant lands, which have been collected by Charcot and his pupils, leave no room for doubt that the peculiarities of hysterical attacks, of hysterogenic zones, of anaesthesia, paralyses and contractures, have been manifested at every time and place just as they were at the Salpêtrière when Charcot carried out his memorable investigation of that major neurosis. '*Transfert*' in particular, which seems to lend itself especially well to proving the suggestive origin of hysterical symptoms, is indubitably a genuine process. It comes under observation in uninfluenced cases of hysteria: one frequently comes across patients in whom what is in other respects a typical hemianaesthesia stops short at one organ or extremity, and in whom this particular part of the body retains its sensibility on the insensible side whereas the corresponding part on the other side has become anaesthetic. Moreover, '*transfert*' is a phenomenon which is physiologically intelligible. As has been shown by investigations in Germany and France, it is merely an exaggeration of a relation which is normally present between symmetrical parts of the body: thus, it can be produced in a rudimentary form in healthy people. Many other hysterical symptoms of sensibility also have their root in normal physiological relations, as has been beautifully demonstrated by the investigations of Urbantschitsch.[2] This is not the proper occasion for carrying out a detailed justification of the symptomatology of hysteria; but we may accept the statement that in essentials it is of a real, objective nature and not falsified by suggestion on the part of the observer. This does not imply any denial that the mechanism of hysterical manifestations is a psychical one: but it is not the mechanism of suggestion on the part of the physician.

Once the existence of objective, physiological phenomena in hysteria has been demonstrated, there is no longer any need to abandon the possibility that hysterical 'major' hypnotism may present phenomena which are not derived from suggestion on the part of the investigator. Whether

1 [Binet & Féré (1884, 1885, 1887).]

2 [Viktor von Urbantschitsch (1847–1921), Professor of Otology at Vienna University.]

these do in fact occur must be left to a further enquiry with this end in view. Thus it lies with the Salpêtrière school to prove that the three stages of hysterical hypnosis can be unmistakably demonstrated even upon a newly arrived experimental subject and even when the most scrupulous behaviour is maintained by the investigator; and no doubt such proof will not be long in coming. For already the description of major hypnotism offers symptoms which tend most definitely against their being regarded
[80] [*Auffassung*] as psychical. I refer to the increase in neuromuscular excitability during the lethargic stage. Anyone who has seen how, during lethargy, light pressure upon a muscle (even if it is a facial muscle or one of the three external muscles of the ear which are never contracted during life) will throw the whole fasciculus concerned into tonic contraction, or how pressure upon a superficial nerve will reveal its terminal distribution – anyone who has seen this will inevitably assume that the effect must be attributed to physiological reasons or to deliberate training and will without hesitation exclude unintentional suggestion as a possible cause. For suggestion cannot produce anything which is not contained in consciousness or introduced into it. But our consciousness knows only of the end result of a movement; it knows nothing of the operation and arrangement of the individual muscles and nothing of the anatomical distribution of the nerves in relation to them. I shall show in detail in a work which is shortly to appear[1] that the characteristics of hysterical paralyses are bound up with this fact and that this is why hysteria shows no paralyses of individual muscles, no peripheral paralyses and no facial paralyses of a central nature. Dr Bernheim should not have neglected to produce the phenomenon of neuromuscular hyperexcitability by means of suggestion; the omission constitutes a serious gap in his argument against the three stages.

Thus physiological phenomena do occur, at all events in hysterical major hypnotism. But in normal minor hypnotism, which, as Bernheim justly insists, is of greater importance for our understanding of the problem, every manifestation – it is maintained – comes about by means of suggestion, by psychical means. Even hypnotic sleep, it seems, is itself a result of suggestion: sleep sets in owing to normal human suggestibility, because Bernheim arouses an expectation of sleep. But there are other occasions, on which the mechanism of hypnotic sleep seems nevertheless to be a different one. Anyone who has hypnotized much will sometimes have come upon subjects who can only be put to sleep with difficulty by talking, while, on the contrary, it can be done quite easily if they are made

1 [In fact, it was not published till five years later: 'Some Points for a Comparative Study of Organic and Hysterical Paralyses' (1893*c*), p. 185 below.]

to fixate[I] [*fixieren*][T] for a little. Indeed, who has not had the experience of a patient falling into a hypnotic sleep whom he has had no intention of hypnotizing and who certainly had no previous conception [*Vorstellung*] [81]
of hypnosis? A female patient takes her place for the purpose of having her eyes or throat examined; there is no expectation of sleep either on the part of the physician or of the patient; but no sooner does the beam of light fall on her eyes than she goes to sleep and, perhaps for the first time in her life, she is hypnotized. Here, surely, any conscious psychical connecting link could be excluded. Our natural sleep, which Bernheim compares so happily with hypnosis, behaves in a similar fashion. As a rule we bring on sleep by suggestion, by mental preparedness and expectation of it; but occasionally it comes upon us without any contribution on our part as a result of the physiological condition of fatigue. So too when children are rocked to sleep or animals hypnotized by being held in a fixed position it can hardly be a question of psychical causation. Thus we have reached the position adopted by Preyer and Binswanger in Eulenburg's *Realencyclopädie*: there are both psychical and physiological phenomena in hypnotism, and hypnosis itself can be brought about in the one manner or the other. Indeed, in Bernheim's own description of his hypnoses there is unmistakably an objective factor independent of suggestion. If this were not so, then, as Jendrássik (1886) logically insists, hypnosis would bear a different appearance according to the individuality of each experimenter: it would be impossible to understand why increase of suggestibility should follow a regular sequence, why the muscular system should invariably be influenced only in the direction of catalepsy, and so on.

We must agree with Bernheim, however, that the partitioning of hypnotic phenomena under the two headings of physiological and psychical leaves us with a most unsatisfied feeling: a connecting link between the two classes is urgently needed. Hypnosis, whether it is produced in the one way or in the other, is always the same and shows the same appearances. The symptomatology of hysteria[2] hints in many respects at a psychical mechanism, though that need not be the mechanism of [82]

1 [This term (which has no relation, of course, to the psychoanalytic use of the same word) means 'to stare fixedly at something'. It is often employed in hypnotic practice. Cf. footnote, p. 152 below.]

2 The relations between hysteria and hypnotism are no doubt very intimate, but they are not so close as to justify one in representing a common hysterical attack as a hypnotic state with several stages, as Meynert (1888*a*, *b*) has done before the Vienna Society of Medicine. In this paper, indeed, a general confusion seems to have been made of our knowledge about these two conditions. For Charcot is spoken of as distinguishing *four* stages of hypnosis, whereas in fact he only distinguishes *three* [see p. 83 f. above], and the fourth, the so-called '*somniant*' stage, is nowhere mentioned except by Meynert. On the other hand, Charcot does ascribe *four* stages to the hysterical attack. [Cf., however, p. 45 *n*. above.]

suggestion. And, finally, suggestion is at an advantage over the physiological events, since its mode of operation is incontestable and comparatively clear, while we have no further knowledge of the mutual influences of the nervous excitability to which the physiological phenomena must go back. In the remarks which follow, I hope to be able to give some indication of the connecting link between the psychical and physiological phenomena of hypnosis of which we are in search.

In my opinion the shifting and ambiguous use of the word 'suggestion' lends to these antitheses a deceptive sharpness which does not in fact exist. It is worthwhile considering what it is which we can legitimately call a 'suggestion'. No doubt some kind of psychical influence is implied by the term; and I should like to put forward the view that what distinguishes a suggestion from other kinds of psychical influence, such as a command or the giving of a piece of information or instruction, is that in the case of a suggestion an idea is aroused in another person's brain which is not examined in regard to its origin but is accepted just as though it had arisen spontaneously in that brain. A classic example of a suggestion of this kind occurs when a physician says to a hypnotized subject: 'Your arm must stay where I put it' and the phenomenon of catalepsy thereupon sets in; or again when the physician raises the patient's arm time after time after it has dropped, and so makes him guess that the physician wants it to be held up. But on other occasions we speak of suggestion where the mechanism of the process is evidently a different one. For instance, in the case of many hypnotized subjects catalepsy sets in without any injunction being given: the arm that has been raised remains raised of its own accord, or the subject maintains the posture in which he went to sleep unaltered unless there is some interference. Bernheim calls this result too a suggestion, saying that the posture itself suggests its maintenance. But in this case the part played by external stimulus is evidently smaller and the part played by the physiological condition of the subject, which disallows any impulse for altering his posture, is greater than in the former cases. The distinction between a directly psychical and an indirect (physiological) suggestion may perhaps be seen more clearly in the following example. If I say to a hypnotized subject: 'Your right arm is paralysed; you cannot move it', I am making a directly psychical suggestion. Instead of this, Charcot gives the subject a light blow on his arm; or says to him: 'Look at that hideous
[83] face! Hit out at it!', the subject hits out, and [in both cases] his arm drops down paralysed.[1] In these two [last] cases an external stimulus has to

1 Charcot (1888) [Lecture VII, Case 1, and Lecture XVIII, Case 1].

begin with produced a feeling of painful exhaustion in the arm; and by this in turn, spontaneously and independently of any intervention on the part of the physician, paralysis has been suggested – if such an expression is still applicable here. In other words, it is a question in these cases not so much of suggestions as of stimulation to *autosuggestions*. And these, as anyone can see, contain an objective factor, independent of the physician's will, and they reveal a connection between various conditions of innervation or excitation in the nervous system. It is autosuggestions such as these that lead to the production of spontaneous hysterical paralyses and it is an inclination to such autosuggestions, rather than suggestibility towards the physician, that characterizes hysteria; and the former does not seem by any means to run parallel with the latter.

I need not insist on the fact that Bernheim too works to a very large extent with indirect suggestions of this sort – that is, with stimulations to autosuggestion. His procedure for bringing about sleep, as described in the opening pages of the present volume, is essentially a mixed one: suggestion pushes open the doors which are in fact slowly opening of themselves for autosuggestion.

Indirect suggestions, in which a series of intermediate links arising from the subject's own activity are inserted between the external stimulus and the result, are nonetheless psychical processes; but they are no longer exposed to the full light of consciousness which falls upon direct suggestions. For we are far more accustomed to bringing our attention to bear upon external perceptions than upon internal processes. Indirect suggestions or autosuggestions can accordingly be described equally as physiological or as psychical phenomena, and the term 'suggestion' has the same meaning as the reciprocal arousing of psychical states according to the laws of association. Shutting the eyes leads to sleep because it is linked to the concept of sleep through being one of its most regular accompaniments: one portion of the manifestations of sleep suggests the other manifestations which go to make up the phenomenon as a whole. This linking up lies in the nature of the nervous system and not in any arbitrary action by the physician; it cannot occur unless it is based upon changes in the excitability of the relevant portions of the brain, in the innervation of the vasomotor centres, etc., and it presents alike a psychological and a physiological aspect. As in the case of every interlinking of states of the nervous system, this one allows of passage [of excitation] in a different direction. The idea of sleep may lead to feelings of fatigue in the eyes and muscles and to the corresponding condition of the vasomotor nerve centres; or on the other hand the condition of the muscular [84]

apparatus or an impact on the vasomotor nerves may in itself cause a sleeper to wake, and so on. All that can be said is that it would be just as one-sided to consider only the psychological side of the process as to attribute the whole responsibility for the phenomena of hypnosis to the vascular innervation.

How does this affect the antithesis between the psychical and the physiological phenomena of hypnosis? There was a meaning in it so long as by suggestion was understood a directly psychical influence exercised by the physician which forced any symptomatology it liked upon the hypnotized subject. But this meaning disappears as soon as it is realized that even suggestion only releases sets of manifestations which are based upon the functional peculiarities of the hypnotized nervous system, and that in hypnosis characteristics of the nervous system other than suggestibility make themselves felt as well. The question might still be asked whether all the phenomena of hypnosis must *somewhere* pass through the psychical sphere; in other words – for the question can have no other sense – whether the changes in excitability which occur in hypnosis invariably affect only the region of the cerebral cortex. By putting the question in this other form we seem to have decided the answer to it. There is no justification for making such a contrast as is here made between the cerebral cortex and the rest of the nervous system:[1] it is improbable that so profound a functional change in the cerebral cortex could occur unaccompanied by significant changes in the excitability of the other parts of the brain. We possess no criterion which enables us to distinguish exactly between a psychical process and a physiological one, between an act occurring in the cerebral cortex and one occurring in the subcortical substance; for 'consciousness', whatever that may be, is not attached to every activity of the cerebral cortex, nor is it always attached in an equal degree to any particular one of its activities; it is not a thing which is bound up with any locality in the
[85] nervous system.[2] It therefore seems to me that the question whether hypnosis exhibits psychical or physiological phenomena cannot be

1 [Freud made a similar point in his aphasia monograph (1891*b*), *NSW*, **4**. Meynert (1884) drew a particularly sharp distinction between cortical and subcortical processes.]

2 [In this connection, it is relevant to quote a footnote added by Freud by way of criticism to a passage in his translation of Bernheim's book (p. 116): 'It appears to me unjustifiable, and unnecessary, to assume that an executive act changes its localization in the nervous system if it is begun consciously and continued later unconsciously. It is, on the contrary, probable that the portion of the brain concerned can operate with a varying quota of attention (or consciousness).' – Cf. a remark of Breuer's in Section 5 of his theoretical contribution to *Studies on Hysteria* (1895*d*), *RSE*, **2**, 203. Freud himself repeated the assertion made in the text above in Section II of his metapsychological paper on 'The Unconscious' (1915*e*), ibid., **14**, 154 f.]

accepted in this general form and that the decision in the case of each individual phenomenon must be made dependent upon a special investigation.

To this extent I feel justified in saying that, whereas on the one hand Bernheim's work goes beyond the field of hypnosis, on the other hand it leaves a portion of its subject matter out of account. But it is to be hoped that German readers of Bernheim, too, will now have the opportunity of recognizing what an instructive and important contribution he has made in thus describing hypnotism from the standpoint of suggestion.

Vienna, August, 1888

APPENDIX

PREFACE TO THE SECOND GERMAN EDITION (1896)[1]

The first edition of this book in German was provided with a Preface by [86]
the translator which it has today become unnecessary to reprint. The scientific situation which at that time confronted the appearance of the translation of Bernheim's *Suggestion* is fundamentally changed today. Doubt of the reality of hypnotic phenomena has grown silent; the proscription has ceased which was then the inevitable fate of any neuropathologist who considered this field of phenomena important and deserving of serious consideration. It has been to no small extent the merit of this book itself to have stood up for the cause of scientific hypnotism in an incomparably convincing and forcible manner.

When the need became apparent for making this fundamental work of the Nancy physician accessible to German readers for a second time, the editor and publisher, in agreement with the author, decided to shorten it by those chapters which contained only case histories and reports of treatments.[2] They could not disguise from themselves that it was not precisely in these that the strength of Bernheim's work lay. Herr Dr M. Kahane then had the kindness to take over from the present writer the task of revising the new edition and of bringing its text into harmony with the latest French edition.

Of the contents of the Preface to the first edition the translator would only like to repeat one remark, to which he adheres no less firmly today than he did then. What he entirely misses in Bernheim's exposition is the view that 'suggestion' (or, rather, the accomplishment of a suggestion) is a *pathological* psychical phenomenon which calls for particular conditions before it can come about. This view need not be upset by the frequency and ease of suggestion nor by the great part it plays in everyday life. In Bernheim's book the establishment of these latter

1 [See p. 80 above.]

2 [This in fact amounted to about half the book; and incidentally the omitted portion coincided with what, as we learn from the 'Postscript' (p. 79 above), had been translated in the first edition by von Springer and not by Freud.]

circumstances as facts takes up so much space that he neglects to raise the psychological problem of when and why the normal methods of psychical
[87] influence between human beings can be replaced by suggestion. And, while he explains all the phenomena of hypnotism by suggestion, suggestion itself remains wholly unexplained, but is veiled by a show of its needing no explanation. This gap has no doubt been observed by all those enquirers who have followed Forel in a search for a psychological theory of suggestion.

DR SIGM. FREUD

REVIEW OF AUGUST FOREL'S *HYPNOTISM*

(1889)

EDITORS' NOTE

REVIEW OF AUGUST FOREL'S *DER HYPNOTISMUS*

GERMAN EDITIONS

1889 *Wien. med. Wschr.*, **39** (28), 1097–100, and (47), 1892–6. (July 13 and November 23.) [90]
1987 *GW*, **Nachtr.**, 125–39.
2015 *SFG*, **2**, 333–45.

ENGLISH TRANSLATION

1966 *SE*, **1**, 91–102. (Tr. James Strachey.)

This is a revised reprint of the *SE* translation.

The full title of Forel's book was *Der Hypnotismus, seine Bedeutung und seine Handhabung* ('Hypnotism, its Significance and its Management'); it was published in 1889 by Ferdinand Enke, Stuttgart. Its author (1848–1931) was at this time Professor of Psychiatry at Zürich and enjoyed a very considerable reputation. His later writings on sociological subjects (and on the natural history of ants) were widely read. Though eventually he became highly critical of psychoanalysis, it was he who introduced Freud to Bernheim. Freud visited Nancy during the summer of 1889, between the publication of the two parts of this review. (Cf. the Editors' Introduction, p. 66 f. above.)

REVIEW OF AUGUST FOREL'S *HYPNOTISM*

I

This work by the celebrated Zürich psychiatrist, only 88 pages long, is [91]
expanded from a paper on the forensic significance of hypnotism which was published in the *Zeitschrift für die gesamte Strafrechtswissenschaft* [Journal of General Penology], **9**, 131, in 1889. It will no doubt retain a prominent place for a long time to come in the German literature of hypnotism. Concise, almost like a catechism in form, expressed with great clarity and decisiveness, it covers the whole field of phenomena and problems which are comprised under the heading of the 'theory of hypnotism'; it distinguishes in the happiest manner between facts and theories, is never lacking in the serious approach demanded of a physician engaged in a thorough investigation, and everywhere avoids the extravagant tone which is so much out of place in a scientific discussion. Only once does Forel's exposition become enthusiastic enough to declare that 'the discovery of the psychological importance of suggestion by Braid[I] and Liébeault is in my opinion so magnificent that it can be compared with the greatest discoveries, or rather revelations, of the human spirit.' Anyone who finds this remark a gross overvaluation of hypnosis should postpone a final judgement till the next few years have made it clear how many of the great theoretical and practical revolutions which hypnosis promises to bring about can in fact result from it. In mentioning the obscure problems bordering upon [*angelehnt*][T] hypnotism (thought transference, etc.) with which 'spiritualism' is at present occupied, Forel exhibits a truly scientific reserve. It is impossible to understand why one authority in this city described the author of this volume, before a scientific audience, as 'Forel the Southerner' and contrasted with him a supposedly 'more Northern' opponent of hypnosis as a model of a cooler mode of thinking. Even if it were less improper to seek to deal with the judgements of living men of science on scientific

Anlehnung

1 [See footnote 2, p. 37 above.]

problems by remarking upon their nationality or native country, and even if Professor Forel had not had the fortune to be born and educated
[92] on the forty-sixth degree of northern latitude,[1] there would be no justification for concluding from the present work that its author is in the habit of allowing his emotions to run away with his logic.

This short study is on the contrary the work of a serious physician who has come to know the value and importance of hypnosis from his own rich experience and has a right to exclaim to 'the scoffers and unbelievers': 'test before you judge!' And we must agree with him when he adds: 'In order to make a judgement about hypnotism one must have practised it for a time oneself.'[2]

There are, to be sure, numerous opponents of hypnosis who have formed their judgement in a more easy-going manner. They have not tested the new therapeutic method and employed it impartially and carefully, as one would, for instance, a newly recommended drug; they have rejected hypnosis *a priori* and now no acquaintance with that procedure's invaluable therapeutic effects hinders them from giving the most biting and unjustified expression to their dislike of it, whatever that may be based on. They immensely exaggerate the dangers of hypnosis, they call it by one bad name after another, and they meet the abundance of reports, which can no longer be overlooked, of cures brought about by hypnosis with oracular pronouncements such as: 'cures prove nothing, they themselves call for proof.'[3] In view of the violence of their opposition, it is not to be wondered at if they accuse those physicians who feel it their duty to make use of hypnosis for the benefit of their patients of disingenuous motives and unscientific modes of thought – accusations which should be excluded from a scientific discussion whether they are brought forward openly or in more or less disguised hints. When among these opponents men are to be found like Hofrat Meynert, men who by their writings have acquired great authority, which is carried over without further enquiry by both the medical and lay public on to all their pronouncements, some damage to the cause of hypnotism is no doubt unavoidable. It is difficult for most people to suppose that a scientist who has had great experience in certain regions of neuropathology, and has given proof of much acumen, should have no qualification for being quoted as an authority on other problems; and

1 As I learn from a letter of Forel's was the case. [He was born at Morges on the Lake of Geneva.]

2 [These are quotations from Forel's preface.]

3 Hofrat Meynert at a meeting of the Gesellschaft der Ärzte [Society of Medicine] on June 7 of this year.

respect for greatness, particularly for intellectual greatness, is certainly among the best characteristics of human nature. But it should yield to [93]
respect for the facts. One need not be afraid to say so openly if one sets aside one's dependence [*Anlehnung*] on an authority in favour of one's own judgement arrived at from a study of the facts.

Anyone who, like the present reviewer, has reached an independent judgement in matters relating to hypnosis will console himself with the reflection that any injury to the reputation of hypnosis that is brought about in this way can only be a limited one both in time and space. The movement which seeks to introduce suggestive treatment into the therapeutic storehouse of medicine has already triumphed in other places and will eventually reach its goal in Germany (and Vienna) too. Any physician who is accessible to considerations of fact will be led to take a less unfavourable attitude when he notices that the supposed victims of hypnotic therapy suffer less after their treatment and can perform their duties better than they did before – as I can assert is the case with my own patients. A few experiments will show them that a whole number of the reproaches that have been levelled against hypnosis apply not in particular to it but to our therapy in general and may indeed be more justifiably directed against particular procedures which we all practise rather than against hypnosis. As physicians, they will discover the impossibility of not practising hypnosis and of allowing their patients to suffer when they can relieve them by a harmless use of psychical influence. They will be obliged to say to themselves that hypnosis loses none of its harmlessness and none of its curative value by being called 'artificial insanity' or 'artificial hysteria', any more than meat loses any of its good taste or nutritive value by being denounced in their rage by vegetarians as 'carrion'.

Let us for a moment forget that we know the effects of hypnosis by experience and let us ask ourselves what injurious effects we would expect *a priori* to result from it. Hypnotic treatment consists in the first place in bringing about a hypnotic state and in the second place in conveying a suggestion to the hypnotized subject. Which of these two acts is supposed to be the injurious one? The bringing about of hypnosis? But hypnosis, when it is most completely successful, is nothing other than ordinary sleep, which is so familiar to us all, even though in many respects, no doubt, it is not yet understood; while, when it is less completely developed, it corresponds to the various stages of falling asleep. It is true that in sleep we lose our psychical equilibrium and that the activity of our brain during sleep is a disordered one and is in many ways reminiscent of insanity; but this analogy does not prevent our awakening from sleep [94]

with renewed strength mentally as well. According to Meynert's views on the injurious effects of reducing cortical activity and the origin he attributes to hypnotic euphoria, we physicians would, in fact, have every reason to keep people in a sleepless condition. But so far people still prefer to sleep and we need not feel afraid that the dangers of hypnotic therapy lie in the act of hypnotizing. Is conveying a suggestion the injurious factor then? That is impossible, for it is a noticeable fact that the opposition's attacks are not in the least directed against suggestion. The use of suggestion, it is alleged, has been something familiar to physicians from time immemorial: 'we are all constantly giving suggestions', they say; and in fact a physician – even a non-hypnotist – is never better satisfied than when he has repressed[1] a symptom from a patient's attention by the power [*Macht*][T] of his personality and the influence of his words – and his authority. Why is it, then, that the physician must not endeavour to achieve systematically the influence which always seems to him so desirable when for once he stumbles on it unawares? But perhaps all the same it is suggestion which is the objectionable thing: the suppression of a free personality by the physician, who also retains a directing power over the sleeping brain in its artificial sleep. It is quite interesting to find the most positive determinists suddenly defending the imperilled 'personal free will', and to hear psychiatrists who are in the habit of suffocating the 'freely aspiring mental activity'[2] of their patients with large doses of bromide, morphine and chloral arraigning suggestive influence as something degrading to both parties. Is it, then, really possible to forget that the suppression of a patient's independence by hypnotic suggestion is always only a partial one, that it is aimed at the symptoms of an illness, that (as has been pointed out a hundred times) the entire social upbringing of human beings is based on a suppression of unserviceable ideas [*Vorstellungen*][T] and motives [*Motive*][T] and their replacement by better ones, and that life daily produces on every individual psychical effects which, even though they impinge on him while he is awake, make far more intense changes in him than does the suggestion of the physician who is trying to get rid of a painful or anxious idea by means of an effective counter-idea? No. There is nothing dangerous in hypnotic therapy but its misuse; and anyone who, as a physician, does not trust the carefulness or purity of his intention to avoid such misuse will do well to keep away from this new therapeutic procedure.

1 ['*verdrängt*.' This is not used, evidently, in what was to become its technical psychoanalytic sense.]

2 [An echo of Meynert (1889, 524).]

As regards the personal assessment of those physicians who have the courage to make use of hypnosis as a therapeutic measure before the high tide of fashion makes it compulsory, the present reviewer is of the opinion that it is fitting to make some allowance for the frequent intolerance of great men. Hence it does not seem to him advisable, or a matter of any sufficient interest to a wider circle, to enquire here into the reasons which led Hofrat Meynert to introduce him [the reviewer] and a part of his life history to the readers of his paper on the traumatic neuroses.[1] [95]

It seems to the reviewer more important to put the case in favour of hypnosis to those who have become accustomed to allowing their judgements on scientific matters to be determined by a great authority and who have perhaps been led into doing so by a correct realization of the inadequacy of their own discernment. This he proposes to do by setting up against the opposing authority of Meynert others who have shown themselves more friendly to hypnosis. He recalls that among us it was Professor H. Obersteiner who first gave an impetus to the scientific study of hypnosis, and that so distinguished a psychiatrist and neurologist as Professor von Krafft-Ebing (a recent acquisition to our University) has declared unreservedly in favour of hypnosis and employs it in his medical practice with the happiest results. It will be seen that these names can satisfy, too, those who are so lacking in judgement that their confidence requires of a scientific authority that it shall fulfil certain conditions as to nationality, race and geographical latitude, and whose faith comes to a stop at the frontier posts of their fatherland.

All those others who are responsive to scientific eminence even from outside the fatherland will count Professor Forel too among the men whose advocacy of hypnosis can reassure them on the alleged baseness and unworthiness of this method of treatment. In particular, the present reviewer has had a feeling when faced with Meynert's attacks that in supporting hypnosis he is in good company. Professor Forel is a proof that a man can be a noteworthy brain anatomist and nevertheless see something in hypnosis other than a piece of absurdity.[2] He too cannot be denied the qualification of being 'a physician trained in precise physiology' – which Hofrat Meynert was gracious enough to confer on the reviewer's past;[3]

1 [Cf. Meynert (1889, 475 and 501 *n*.).]

2 [Meynert used this term. See p. 81 above.]

3 I must again set Hofrat Meynert right. He says of me that I am 'working in this place as a trained practitioner in hypnosis'. This says too little, and it might create a false impression among strangers that I do nothing else but hypnotize. On the contrary, I work 'in this place' as a nerve specialist and I make use of all the therapeutic methods which are at the disposal of such workers. The results which I have hitherto obtained from the use of hypnosis make it my duty, however, not to abandon this powerful expedient henceforward.

[96] and just as the reviewer returned here in a depraved state from the wickedness of Paris, so a journey to Bernheim in Nancy was the starting point for Professor Forel of the fresh activity to which we owe the present excellent work.

II

In the opening sections of his book Forel endeavours so far as possible to distinguish between 'facts, theories, concepts and terminology'.

The main fact of hypnotism lies in the possibility of putting a person into a particular condition of mind [*Seele*][T] (or, more precisely, of brain) which resembles sleep. This condition is known as hypnosis. A second set of facts lies in the manner in which this condition is brought about (and ended). This appears to be possible in three ways: (1) by the psychical influence of one person on another (suggestion), (2) by the (physiological) influence of certain procedures (fixating[I]), by magnets, the human hand, etc., and (3) by self-influence (autosuggestion). Only the first of these methods is, however, established: production by ideas – suggestion. In none of the other ways of producing hypnosis does the possibility seem to be excluded of the action of suggestion in some form or other.

A third set of facts concerns the performance of the hypnotized person. For it is possible in the condition of hypnosis to exercise the most extensive effects by means of suggestion on almost all the functions of the nervous system and among them on activities whose dependence on processes in the cerebrum is as a rule estimated too low. The fact that the influence of the cerebrum on somatic functions can be made use of more intensively under hypnosis than in the waking state harmonizes little, it is true, with those theories of hypnotic phenomena which seek to regard them as a 'depressing of cortical activity', a kind of experimental imbecility. But there are a number of other things, apart from hypnotic phenomena, that do not harmonize with this theory, which seeks to understand almost all the phenomena of cerebral activity by means of the contrast between 'cortical' and 'subcortical', and seems to go so far as to locate the 'evil' principle in the subcortical portions of the brain.[2]

[97] Further unquestionable facts are the dependence of the hypnotized subject's mental activity on that of the hypnotist and the production of what are known as 'post-hypnotic' effects in the former – that is, the

1 [See footnote 1, p. 87 above.]

2 [See footnote 1, p. 90.]

determining of psychical acts which are only carried out a considerable time after the hypnosis has ceased. On the other hand, there are a whole number of assertions which report the most interesting performances by the nervous system (clairvoyance, mental suggestion, etc.) but which cannot today be included among the facts; and although a scientific examination of these assertions should not be refused, it must be borne in mind that their satisfactory clarification involves the greatest difficulties.

Three fundamentally different theories have been set up to explain the phenomena of hypnosis. The oldest of these, which we still call after Mesmer,[1] supposes that, in the act of hypnotizing, an imponderable material – a fluid – passes over from the hypnotist into the hypnotized organism. Mesmer called this agent 'magnetism'. His theory has become so alien to our contemporary mode of scientific thought that it may be considered as eliminated.[2] A second, somatic, theory explains hypnotic phenomena on the pattern of spinal reflexes; it regards hypnosis as a physiologically altered condition of the nervous system brought about by external stimuli (stroking, fixating of sensory activity, adduction of magnets, application of metals, etc.). It asserts that stimuli of this kind only have a 'hypnogenic' effect when there is a particular disposition of the nervous system and therefore that only neuropaths (especially hysterics) are hypnotizable. It disregards the influence of ideas in hypnosis and describes a typical series of purely somatic changes which are to be observed during the hypnotic state. As is well known, it is the great authority of Charcot which supports this exclusively somatic view [*Auffassung*][T] of hypnosis.

Forel, however, takes his stand entirely on a third theory – the theory of suggestion erected by Liébeault and his pupils (Bernheim, Beaunis, Liégeois). According to this, all the phenomena of hypnosis are psychical effects, effects of ideas which are provoked in the hypnotized subject either intentionally or not. The state of hypnosis itself is produced not by

1 [In the original the name is spelt 'Messmer'. Franz Anton Mesmer (1713–1815) was a German, who trained and practised as a doctor in Vienna. He asserted the existence of an animal magnetism – as distinct from mineral magnetism – and its efficacy in treating disease. The hostility he aroused in Vienna drove him to Paris in 1778, where, despite strong attacks by the medical establishment, he found many supporters. His views gained surprising ground among academic scientists and the medical profession in Germany, and magnetism was also adopted by doctors in Russia, Denmark and Holland. In France, mesmerism was mostly practised by lay therapists. In Switzerland and Italy, however, it aroused little interest, and Austria remained implacably opposed. The subject attracted no serious attention in England until the investigations of Braid in the 1840s (cf. p. 37 *n.* 2 above) at a time when it was on the wane in the rest of Europe. Mesmer's own book (1779) probably gives the fullest account of his theories.]

2 [Freud (1904*d*) made some interesting further remarks in this connection. See *RSE*, 7, 317.]

external stimuli but by a suggestion; it is not peculiar to neuropaths, but can be achieved with little trouble in the great majority of healthy people. In short, 'the concept of hypnotism, which has hitherto been so ill-defined, must dissolve into that of suggestion.' Whether the concept of suggestion is in fact less ill-defined than that of hypnotism must be
[98] reserved for the decision of a more exhaustive criticism.[1] Here it need only be remarked that a physician who desires to study hypnosis and form an opinion on it will undoubtedly be best advised to adopt the suggestion theory from the first. For he will be able to convince himself of the correctness of the assertions of the school of Nancy at any time on his own patients, whereas he is scarcely likely to find himself in a position to confirm from his own observation the phenomena described by Charcot as 'major hypnotism', which seem only to occur in a few sufferers from *grande hystérie*.[2]

The second section of the book deals with suggestion, and covers, with admirable conciseness and a masterly and penetrating power of description, the whole field of the psychical phenomena that have been observed in subjects [*Personen*][T] under hypnosis. The key to the understanding of hypnosis is offered by Liébeault's theory of normal sleep (or, rather, of normal falling asleep), from which hypnosis is distinguished only by the insertion of the relationship between the subject and the person who puts him to sleep. It follows from this theory that everyone is hypnotizable and that for hypnosis not to come about calls for the presence of special obstacles. The nature of these obstacles (a too intense wish to be hypnotized not less than deliberate recalcitrance, and so on) is considered, the degrees of hypnosis are discussed, the relation of suggested sleep to the other phenomena of hypnosis is reviewed, for the most part in complete agreement with Bernheim, whose authoritative work on suggestion seems to have found a wide circle of readers in its German translation.[3] The paragraphs on the effects of suggestion under hypnosis are similarly presented in the form of extracts from Bernheim, but they are invariably illustrated by examples from the author's own experience. Forel introduces them with this sentence: 'By means of suggestion under hypnosis it is possible to produce, influence, hinder (inhibit, modify, paralyse or stimulate) all the known subjective phenomena of the human mind and a large part of the objectively known functions of the nervous system' – that is, to influence the sensory and motor functions of the body, certain

1 [See, however, p. 109 below.]

2 [Cf. p. 83 above.]

3 [This translation, by Freud himself, had only recently appeared (Freud, 1888–89*a*). See the introduction to it, p. 81 above.]

reflexes and vasomotor processes (even to the extent of raising blisters!), and, in the psychical sphere, feelings, drives [*Triebe*][T], memory, volitional activity and so on. Anyone who has assembled a few personal experiences with hypnotism will recall the impression it made on him for the first time he exercised what had hitherto been an undreamt-of influence on another person's psychical life and was able to experiment on a human [99] mind in a way that is normally possible only on an animal's body. It is true that this influence is effected only rarely without resistance on the part of the hypnotized subject. He is no mere automaton; he often puts up a fight against suggestion and by his own activity creates 'autosuggestions' – a term which, incidentally, only *appears* to be an enrichment of the concept of 'suggestion' but is, strictly speaking, an abrogation of it.

Of the greatest interest are the discussions which follow concerning post-hypnotic phenomena, suggestions due to take effect after a fixed time limit and suggestion in the waking state – a group of phenomena the study of which has already yielded the most valuable conclusions about normal psychical processes in human beings, though their interpretation [*Auffassung*] is still subject to some dispute. If the work of Liébeault and his pupils had produced nothing more than the knowledge of these remarkable, though at the same time everyday, phenomena and this enrichment of psychology by a new experimental method, then, even apart from any practical bearing, they would already be assured of a prominent place among the scientific discoveries of this century. Forel's little book contains a whole number of pertinent remarks and pieces of advice on the practical application of hypnotism, which compel the fullest appreciation of the author. Only a physician who combines the most complete mastery of this difficult subject with a firm conviction of its importance could write in this way. The technique of hypnotism is not as easy as one might be led to suppose by the well-known criticism advanced at the first Berlin discussion: 'hypnotizing is not a medical skill, since every shepherd boy practises it.' One must be armed with enthusiasm, patience, great certainty and a wealth of stratagems and inspirations. Anyone who tries to hypnotize according to a ready-made pattern, who is afraid of his subject's distrust or laughter, or who starts off in a half-hearted mood, will achieve little. The subject who is to be hypnotized must not be nervously left in the lurch; very nervous people are the least suited for carrying out this kind of treatment. A competent and steady procedure will suppress all the alleged evil consequences of hypnotism. As

Dr Bérillon has aptly said: 'On ne s'improvise pas plus médecin hypnotiseur qu'on ne s'improvise oculiste'.[1]

And now, what can be achieved by hypnosis? Forel gives a list of disorders 'which seem to yield best to suggestion' without wishing to claim it as exhaustive. It should be added that the position occupied by
[100] 'indications' in the case of hypnotic treatment is of a somewhat different kind from what it is in such cases as the use of digitalis, for instance. It depends almost more on the characteristics of the subject than on the nature of his illness. With one person there is scarcely a symptom that does not yield to suggestion, however firm its organic basis – for instance, the vertigo in Ménière's disease or the cough in tuberculosis;[2] with another person it is impossible to influence even disorders with an undoubted psychical causation. Not less depends on the dexterity of the hypnotist and the conditions under which he is able to treat his patients. I myself have had not a few happy results from hypnotic treatment; but I do not venture to undertake some cures of a sort which I have witnessed under Liébeault and Bernheim at Nancy. I know too that a good part of this success is due to the 'suggestive atmosphere' which surrounds the clinic of these two physicians, to the milieu and to the mood of the patients – things which I cannot always replicate for the subjects of my experiments.

Is it possible to change a nervous function permanently by suggestion? Or is the reproach justified which alleges that suggestion only produces symptomatic successes for a short time? Bernheim himself has given an incontrovertible reply to this reproach in the last paragraphs of his book. He points out that suggestion operates in the same manner as any other therapeutic agent which we have at our disposal: that is, it chooses out from a complex of pathological phenomena one important symptom or another the removal of which will exercise the most favourable influence on the course of the whole process. It may be added that suggestion furthermore satisfies all the requirements of a causal treatment[3] in a number of cases. This is so, for instance, in hysterical disorders, which are the direct result of a pathogenic idea or the deposit of a shattering experience. If that idea is got rid of or that memory weakened – which is what suggestion brings about – the disorder too is usually overcome.[4] It

1 ['One cannot turn oneself into a medical hypnotist on the spur of the moment any more than into an oculist.']

2 [Cf. Freud's (1887*n*) review of Berkhan, p. 37 above.]

3 [Freud discussed the nature of causal treatment and the question of whether psychoanalysis satisfied its conditions in Lecture XXVII of the *Introductory Lectures* (1916–17*a*), *RSE*, **16**, 385.]

4 [A probable reference to Breuer's technique.]

is true that this does not mean that the hysteria is cured: in similar conditions it will provoke similar symptoms. But is hysteria cured, then, by hydrotherapy, by feeding-up or by valerian? When is a physician ever expected to cure a nervous diathesis if the circumstances which promote it persist? According to Forel, a permanent success can be achieved by suggestion on the following conditions: (1) If the change brought about has *within itself* the strength [*Kraft*] to maintain itself among the dynamics of the nervous system. Suppose, for instance, a child has been [101]
broken of bedwetting by suggestion. Then the normal habit can establish itself as firmly as the previous bad one. Or (2) if this strength is *supplied* to the change by a remedy. Suppose, for instance, that someone suffers from insomnia, fatigue and migraine. Then suggestion assures him of sleep and thus improves his general condition and the return of the migraine is permanently prevented.

But what in fact *is* this suggestion, which is the basis of the whole of hypnotism, in which all these results are possible? By raising this question we touch one of the weak sides of the Nancy theory. We are involuntarily reminded of the question of where St Christopher stood[1] when we find that Bernheim's exhaustive work, which culminates in the statement 'Tout est dans la suggestion', nowhere attempts to touch upon the nature of suggestion – that is, upon a definition of the concept. When I was in the fortunate position of being instructed personally by Professor Bernheim on the problems of hypnotism, I seemed to see that he called *every* effective psychical influence exercised by one person on another a suggestion, and that he called *every* effort to exercise a psychical influence on someone else 'suggesting'. Forel endeavours to make a sharper distinction. A section on 'Suggestion and Consciousness', which is rich in ideas, seeks to understand the operation of suggestion on the basis of certain fundamental hypotheses about normal psychical events. Even if we are not called on to declare ourselves completely satisfied by this discussion, we nevertheless owe the author our thanks for pointing out the direction in which a solution to the problem is to be looked for, and for numerous pointers and contributions towards it. There can be no doubt that remarks such as those made by Forel in this section of his book have more to do with the problem of hypnosis than have the contrast between 'cortical and subcortical' and speculations on the dilatation and constriction of the cerebral blood vessels.

1 [An old conundrum: 'Christopher bore Christ; Christ bore the whole world; where then did Christopher stand?' More than thirty years later Freud quoted this again in exactly the same connection, in the discussion of suggestion in Chapter IV of his *Group Psychology* (1921*c*), *RSE*, **18**, 84.]

A section on the forensic significance of suggestion concludes the volume. 'Suggested crimes' are hitherto, as we know, merely a possibility, for which jurists are preparing themselves and which novelists may anticipate as 'not so improbable that they might not happen some time'. To be sure, it is not difficult in a laboratory to induce good somnambu-
[102] lists to commit imaginary crimes. But how far the subject's consciousness that it is only a question of experiment facilitates the commission of the crime is a question which, after Delboeuf's shrewd criticism of Liégeois's[1] experiments, must be left an open one.

DR SIGM. FREUD

1 [Jules Liégeois, Professor of Jurisprudence at the University of Nancy, gives an account of these experiments, in which he induced hypnotized subjects to commit harmless 'murders' with ineffectual weapons and other crimes (Liégeois, 1884). See also his book (1889), which goes deeper into the forensic implications of the subject. Liégeois believed in and feared the possibility of crime induced under hypnosis or following post-hypnotic suggestion. Delboeuf, following Charcot, denied it, pointing out that the behaviour of these somnambulists would have been coloured by the knowledge that the experiments were, so to speak, a 'game' and that the supremely respectable Professor Liégeois would never cause them to do anything really wicked. When Liégeois attacked Delboeuf for underestimating the potential danger, the latter counterattacked with a charge of exaggeration of the risks involved. Cf. Delboeuf (1886, 1888).]

ENGLISH TRANSLATION

1966 *SE*, **1**, 105–14. (Tr. James Strachey.)

The 2nd and 3rd German editions are unaltered, except for a very few extremely small corrections, mainly typographical. The present translation is a revised reprint of the *SE* version.

This signed contribution to a medical dictionary had been entirely overlooked till it was discovered in 1963 by Dr Paul F. Cranefield, the editor of the *Bulletin* of the New York Academy of Medicine. Our thanks are due to him for drawing attention to it. Nothing seems to be known of the circumstances of its composition.

Anton Bum was editor of the *Wiener medizinische Presse* in which, two years later, Freud's lecture 'On the Psychical Mechanism of Hysterical Phenomena' (1893*h*) was published. See *RSE*, **3**, 27.

HYPNOSIS

It would be a mistake to think that it is very easy to practise hypnosis for [105]
therapeutic purposes. On the contrary, the *technique* of hypnotizing is just as difficult a medical procedure as any other. A physician who wishes to hypnotize should have learnt it from a master of the art and even then will require much practice of his own in order to achieve successes in more than a few isolated cases. Afterwards, as an experienced hypnotist, he will approach the matter with all the seriousness and decisiveness which spring from a consciousness of undertaking something useful and, indeed, in some circumstances necessary. The recollection of so many cures brought about by hypnosis will lend his behaviour towards his patients a certainty which will not fail to evoke in them too an expectation of yet another therapeutic success. Anyone who sets about hypnotizing half-sceptically, who may perhaps seem comical to himself in this situation, and who reveals by his expression, his voice and his bearing that he expects nothing from the experiment, will have no reason to be surprised at his failures, and should rather leave this method of treatment to other physicians who are able to practise it without feeling damaged in their medical dignity, since they have convinced themselves, by experience and reading, of the reality and importance of hypnotic influence.

We should make it a rule not to seek to impose hypnotic treatment on any patient. A prejudice is widespread among the public (actually supported by some eminent, but in this matter inexperienced, physicians[1]) that hypnosis is a dangerous operation. If we sought to impose hypnosis on someone who believed this assertion, we should probably be interrupted, after no more than a few minutes, by disagreeable occurrences, which would arise from the patient's anxiety [*Angst*][T] and his distressing feeling of being overpowered, but which would quite certainly be regarded as results of hypnosis. Whenever, therefore, a violent resistance arises against the use of hypnosis, we should renounce the method and

1 [Cf. Freud's criticism of Meynert in his review of Forel, p. 100 ff. above.]

wait till the patient, under the influence of other information, becomes reconciled to the idea of being hypnotized. On the other hand, it is not at all unfavourable if a patient declares that he is not afraid of hypnosis, but that he does not believe in it or does not believe that it can be of use
[106] to him. In such a case we say to him: 'I do not require your credence, but only your attention and some compliance at the start.' And as a rule we find excellent support in this indifferent mood of the patient. On the other hand, it must be said that there are people who are hindered from falling into hypnosis precisely by their willingness and their insistence upon being hypnotized. This is completely out of harmony with the popular view that 'faith' is a factor in hypnosis, but such are the facts. We may in general start from the assumption that everyone is hypnotizable; but every individual physician will be unable to hypnotize a certain number of people under the conditions of his experiments, and will often be unable to say where his failure lay. Occasionally one procedure is successful in achieving something which seemed to be impossible with another one, and the same is true of different physicians. We can never tell in advance whether or not it will be possible to hypnotize a patient, and the only way we have of discovering is by the attempt itself. There has been no success hitherto in bringing accessibility to hypnosis into relation with any other of an individual's attributes. All that is true is that sufferers from mental disease and degenerates are for the most part not hypnotizable, and neurasthenics only with great difficulty; it is untrue that hysterical patients are unadapted for hypnosis. On the contrary, it is precisely the latter in whom hypnosis comes about in response to purely physiological measures and with all the appearance of a special physical condition. It is important to form a provisional judgement of the psychical individuality of a patient whom we wish to hypnotize; but general rules on this particular point cannot be laid down. It will be clear, however, that there is no advantage in beginning a medical treatment with hypnosis, and that it is better first of all to gain the patient's confidence and to allow his distrust and critical sense to blunt themselves. Anyone who enjoys a great reputation as a physician or as a hypnotist can, however, do without this preparation.

Against what illnesses are we to make use of hypnosis? Indications on this are more difficult than in the case of other methods of treatment, since individual reaction to hypnotic therapy plays almost as great a part as the nature of the illness that is to be combated. In general, we shall avoid applying hypnotic treatment to symptoms which have an organic basis and shall employ this method only for purely functional, nervous

disorders, for ailments of psychical origin and for toxic as well as other addictions. We shall, however, become convinced that quite a number of symptoms of organic diseases are accessible to hypnosis and that organic change can exist without the functional disturbance which proceeds [107] from it. In view of the dislike of hypnotic treatment prevailing at present, it seldom comes about that we can employ hypnosis except after all other kinds of treatment have been tried without success. This has its advantage, since we come to know in this way the true sphere of action of hypnosis. We can of course also hypnotize for purposes of differential diagnosis: for instance, when we are in doubt as to whether certain symptoms relate to hysteria or to an organic nervous illness. This test, however, is of some value only in cases where the outcome is favourable.

When we have made our patient's acquaintance and established the diagnosis, the question arises of whether we are to undertake the hypnosis in a tête-à-tête or to introduce a trustworthy third person. This measure would be desirable to protect the patient from an abuse of hypnosis as well as to protect the physician from being accused of it. And both of these things are on record. But it cannot be applied universally. The presence of a woman friend, of the patient's husband, and so on, often disturbs the patient very considerably and decidedly diminishes the physician's influence. Moreover, the subject matter of the suggestions which are to be imparted in the hypnosis is not always suitable for conveyance to other people closely connected with the patient. The introduction of a second physician would not have this disadvantage, but it increases the difficulty of carrying out the treatment so much that it becomes impossible in the majority of cases. Since it is the physician's foremost duty to be of assistance by means of the hypnosis, he will in most cases renounce the introduction of a third person and will lump in the danger that has been mentioned with the others that are inherent in the practice of the medical profession. The patient, however, will guard herself by not allowing herself to be hypnotized by any physician who does not seem to deserve the fullest confidence.

On the other hand, it is of the greatest value for the patient who is to be hypnotized to see other people under hypnosis, to learn by imitation how she is to behave and to learn from others the nature of the sensations during the hypnotic state. In Bernheim's clinic and in Liébeault's outpatient clinic at Nancy, where every physician can obtain enlightenment concerning the results of which hypnotic influence is capable, hypnosis is never conducted in a tête-à-tête. Every patient who is making his first acquaintance with hypnosis watches for a while how older patients fall

asleep, how they are obedient during hypnosis and how, after waking up, they admit that their symptoms have disappeared. This brings him into a
[108] condition of psychical preparedness, which causes him, for his part, to fall into deep hypnosis as soon as his turn comes. The objection to this procedure lies in the fact that the ailments of each individual are discussed before a large crowd, which would not be suitable with patients of a higher social class. Nevertheless, a physician who wishes to treat by hypnosis should not renounce this powerful assisting factor, and should, so far as this is possible, arrange for the person who is to be hypnotized to be present first at one or more successful hypnotic experiments. If we cannot count on the patient hypnotizing himself by imitation as soon as we give him the signal, we have a choice between various *procedures* for bringing him under hypnosis, all of which have in common the fact that they recall falling asleep through certain physical sensations. The best manner of proceeding is as follows. We place the patient in a comfortable chair, ask him to attend carefully and not to speak any more, since talking would prevent his falling asleep. Any tight clothing is taken off and any other people present are placed in a part of the room where they cannot be seen by the patient. The room is darkened, silence is preserved. After these preparations, we sit down opposite the patient and request him to fixate[1] on two fingers of the physician's right hand and at the same time to observe closely the sensations which develop. After quite a short time, a minute, perhaps, we begin to talk the patient into feeling the sensations of falling asleep. For instance: 'I see that things are going quickly in your case: your face has taken on a rigid look, your breathing has become deeper, you have grown quite peaceful, your eyelids are heavy, your eyes are blinking, you can no longer see clearly, you will have to swallow soon, then you will close your eyes – and you are asleep.' With these and similar words we are already well into the process of 'suggesting', as we call such persuasive remarks during hypnosis.[2] But we are only suggesting sensations and motor processes such as occur spontaneously at the onset of hypnotic sleep. We can convince ourselves of this if we have someone before us who can be put under hypnosis by fixating alone (the method of Braid), in whom, accordingly, the fatigue of the eyes, owing to the straining of attention and its diversion from other impressions, brings on the sleeplike state. First the patient's face
[109] assumes a rigid look, his breathing deepens, his eyes grow moist and

1 [See footnote 1, p. 87 above.]

2 [Unlike French and English (in which the technical use of the term 'suggestion' was derived from its everyday use), German adopted the word first in its technical sense and only subsequently and rarely introduced it into ordinary language.]

blink frequently, one or more swallowing movements occur, and finally the eyeballs turn inwards and upwards, the eyelids fall, and hypnosis is there. The number of such people is very considerable; if we observe that we have someone of this kind before us, we shall be well advised to keep silent or only to give occasional help with a suggestion. Otherwise we should merely be disturbing the patient who is hypnotizing himself, and, if the succession of suggestions does not correspond to the actual course of his sensations, we should be provoking contradiction. In general, however, it is advisable not to wait for a spontaneous development of hypnosis but to encourage it by suggestions. These must, however, be given energetically and in rapid succession. The patient should not, as it were, come to his senses: he should not have time to test whether what is said to him is correct. We do not need more than from two to four minutes for his eyes to close; if they have not closed spontaneously, we close them by pressure on them, without showing surprise or annoyance at their spontaneous closure not having come about. If the eyes then remain closed, we have as a rule achieved a certain degree of hypnotic influence. This is the decisive moment for all that is to follow.

For one of two possibilities has come about. The first alternative is that the patient, by fixating and listening to the suggestions, has really been brought under hypnosis, in which case he remains quiet after the closure of his eyes. We may then test him for catalepsy, give him the suggestions called for by his ailment, and thereupon awaken him. After waking up he will either be amnesic (that is to say, he has been 'somnambulistic' during the hypnosis), or he will retain his memory completely and report on his sensations during the hypnosis. Not infrequently a smile appears on his features after we have closed his eyes. The physician should not be put out by this; as a rule it only means that the person under hypnosis is still able to form a judgement on his own state and finds it peculiar or comical. The second alternative, however, is that no influence, or only a slight degree of it, has been established, while the physician has behaved as though he had a successful hypnosis before him. Let us picture the patient's mental state [*Seelenzustand*][T] at this point. He has promised at *Seele*
the start of the preparations to stay quiet, not to speak any more and to give no indication of confirmation or contradiction; he now notices that, on the basis of his consent to this, he is being told that he is hypnotized; he is irritated at this, feels uncomfortable at not being allowed to express his irritation; no doubt, too, he is afraid that the physician will begin suggesting to him too soon, in the belief that he is hypnotized before he [110]
is. And now experience shows that, if he is not really hypnotized, he does

not keep to the compact we have made with him.[1] He opens his eyes and says (resentfully, as a rule): 'I am not in the least asleep!' A beginner would now regard the hypnosis as a failure, but someone with experience will not lose his composure. He will reply, not in the least angrily, as he once more closes the patient's eyes: 'Keep still. You have promised not to talk. Of course I know that you are not "asleep"; nor is that in the least necessary. What would have been the sense of my simply making you fall asleep? You would not understand when I speak to you. You are not asleep, but you are hypnotized, you are under my influence; what I say to you now will make a special impression on you and will be of use to you.' After this explanation, the patient usually becomes quiet and we make the suggestions to him; for the moment we abstain from looking for physical signs of hypnosis, but, after this so-called hypnosis has been repeated a number of times, we shall find that some of the somatic phenomena which characterize hypnosis will emerge.

In many cases of this kind it remains to the end doubtful whether the state we have provoked deserves the name of 'hypnosis'. We should be wrong, however, if we sought to restrict the making of suggestions to those other cases in which the patient becomes somnambulistic or falls into a deep degree of hypnosis. In cases like these, which in fact only have the *appearance* of hypnosis, we can achieve the most astonishing therapeutic results, which, on the other hand, are not to be obtained by 'waking suggestion'. Here too, therefore, it must nevertheless be a question of hypnosis – whose only purpose, after all, is the effect which is brought about in it by suggestion. If, however, after repeated attempts (from three to six) there is neither a hint of success nor any of the somatic signs of hypnosis, we shall give up the experiment.

Bernheim and others have distinguished several degrees of hypnosis, whose enumeration is of little value in practice. What is of decisive importance is only whether or not the patient has become somnambulistic – that is, whether the state of consciousness brought about in the hypnosis is cut off from the ordinary one sufficiently sharply for the memory of what occurred during hypnosis to be absent after waking. In these cases the physician can deny the reality of the pains that are present, or of any other symptoms, with the greatest decision – which he is as [111] a rule unable to do if he knows that a few minutes later the patient will say to him: 'When you said I no longer had any pains, I did have them all

1 [Cf. a phrase in one of the very last of Freud's papers, 'Analysis Terminable and Interminable' (1937*c*), *RSE*, **23**, 215: 'During the work on the resistances the ego withdraws . . . from the agreement on which the analytic situation is founded.']

the same and I still have them now.' The hypnotist's efforts are directed to sparing himself contradictions of this sort which are bound to shake his authority. It would therefore be of the greatest importance for treatment if we possessed a procedure which made it possible to put *anyone* into a state of somnambulism. Unluckily there is no such procedure. The chief deficiency of hypnotic therapy is that it cannot be dosed. The degree of hypnosis attainable does not depend on the physician's procedure but on the chance reaction of the patient. It is very difficult, too, to deepen the hypnosis into which a patient falls, though this usually happens when there are frequently repeated sessions.

If we are not satisfied with the hypnosis attained, we shall look for other procedures when the treatment is repeated. These often work more strongly or continue to work after the influence of the procedure first adopted has grown weaker. Here are some such procedures: stroking the patient's face and body with both hands continuously for from five to ten minutes (this has a strikingly soothing and lulling effect); suggestion accompanied by the passage of a weak galvanic current, which produces a perceptible sensation of taste (the anode in a broad band on the forehead and the cathode in a band round the wrist) – here the impression of being tied up and the galvanic sensation contribute greatly towards hypnosis. We can invent similar procedures at our choice if we only keep the aim before us of arousing, by an association of thought, the picture of falling asleep and of fixating attention by means of a persistent sensation.

The true therapeutic value of hypnosis lies in the *suggestions* made during it. These suggestions consist in an energetic denial [*Verneinung*] of the ailments of which the patient has complained, or in an assurance that he can do something, or in a command to perform it. A far more powerful result than that produced by a simple assurance or denial is achieved if we link the expected cure to an action or intervention [of our own] during hypnosis. For instance: 'You no longer have any pains at this place; I press on it and the pain has gone.' Stroking and pressing on the ailing part of the body during hypnosis gives excellent support in general to the spoken suggestion. Nor should we neglect to enlighten the patient under hypnosis on the nature of his ailment, to give him reasons for the cessation of his trouble, and so on; for what we have before us is not, as a rule, a psychical automaton, but a being endowed with the power of criticism and capacity [112]
for judgement, on whom we are simply in a position to make more impression now than when he is in a waking state. Where hypnosis is incomplete, we should avoid allowing the patient to speak. Motor utterance of this sort dissipates the numbed feeling which vouches for his hypnosis and

wakes him up. Somnambulistic subjects may without fear be allowed to speak, walk about and work, and we obtain the most far-reaching psychical influence over them by questioning them under hypnosis about their symptoms and the origin of these.[1]

Through suggestion we call for either an immediate effect – particularly in treating paralyses, contractures, and so on – or a post-hypnotic effect – that is, one which we stipulate for a particular time after awakening. In the case of all obstinate ailments it is a great advantage to interpolate a waiting period like this (even a whole night) between the suggestion and its execution. Observation of patients shows that psychical impressions as a rule need a certain time, an incubation period, in order to bring about a physical change. (Cf. 'Neurosis, traumatic'.)[2] Each separate suggestion must be made with the greatest decisiveness, for any hint of a doubt is noticed by the patient and unfavourably exploited; no contradiction whatever must be permitted and, if we are able, we should insist upon our power to produce catalepsy, contractures, anaesthesia, and so on.

The *duration* of a hypnosis is to be arranged according to practical requirement; a comparatively long continuance under hypnosis – up to several hours – is certainly not unfavourable to success. Awakening is brought about by some such remark as: 'That is enough for the present!' We should not fail to give an assurance at the first hypnosis that the patient will wake up without a headache, cheerful and well. In spite of this, it can be observed that, after a light hypnosis, many people wake up with pressure in the head and fatigue, if the duration of the hypnosis has been too short. They have not, as it were, had their sleep out.

The *depth* of a hypnosis is not invariably in direct proportion to its success. We may produce the greatest changes in the lightest hypnosis and, on the contrary, we may have a failure under somnambulism. If the desired success is not achieved after a few hypnoses, a further difficulty is revealed which attaches to this method of treatment. Whereas no patient ventures to be impatient if he has still not been cured after the
[113] twentieth electrical session or an equal number of bottles of mineral water, with hypnotic treatment both physician and patient grow tired far sooner, as a result of the contrast between the deliberately rosy colouring of the suggestions and the cheerless truth. Here, too, intelligent patients can make it easier for the physician as soon as they have understood that in making suggestions he is, as it were, playing a part and that the more

1 [This is again an allusion to Breuer's method, which Freud was already using at the time he wrote this article.]

2 [The reference is to another article in Bum's *Lexikon*.]

energetically he disputes their ailment the more advantage is to be expected for them. In every prolonged hypnotic treatment a monotonous procedure is carefully to be avoided. The physician must constantly be on the look-out for a new starting point for his suggestions, a new proof of his power, a new change in his hypnotizing procedure. For him too, who has, perhaps, internal doubts about success, this presents a great and in the end exhausting strain.

There is no doubt that the field of hypnotic treatment is far more extensive than that of other methods of treating nervous illnesses. Nor is there any justification for the reproach which asserts that hypnosis is only able to influence symptoms and them only for a short time. If hypnotic treatment is directed only against symptoms and not against pathological processes, it is following precisely the same path which all other therapeutic methods are obliged to take.

If hypnosis has had success, the stability of the cure depends on the same factors as the stability of every cure achieved in another way. If what it was dealing with were residual phenomena of a process that was concluded, the cure will be a permanent one; if the causes which produced the symptoms are still at work with undiminished strength, then a relapse is probable. The employment of hypnosis never excludes that of any other treatment, dietetic, mechanical, or of some other sort. In a number of cases – namely where the symptoms are of purely psychical origin – hypnosis fulfils all the demands that can be made of a causal treatment,[1] and in that case questioning and calming the patient in deep hypnosis is as a rule accompanied by the most brilliant success.

Everything that has been said and written about the great *dangers* of hypnosis belongs to the realm of fable.[2] If we leave on one side the misuse of hypnosis for illegitimate purposes – a possibility that exists for every other effective therapeutic method – the most we have to consider is the tendency of severely neurotic people, after repeated hypnosis, to fall into hypnosis spontaneously. It is in the physician's power to forbid this spontaneous hypnosis, which would seem to come about only in very susceptible individuals. People whose susceptibility goes so far that they can be hypnotized against their will can also be protected fairly completely by a suggestion that only their physician will be able to hypnotize them.[3] [114]

FREUD

1 [See footnote 3, p. 108 above.]

REPORT OF A LECTURE 'ON HYPNOSIS AND SUGGESTION'

(1892)

EDITORS' NOTE

ÜBER HYPNOSE UND SUGGESTION

GERMAN EDITIONS

1892 *Int. klin. Rdsch.*, **6** (20), 814–18, and (21), 853–6.
1987 *GW*, **Nachtr.**, 166–78.

The present translation, by Mark Solms, is the first into English.

This is an original report of a lecture delivered by Freud before the Wiener Medizinischer Club (Vienna Medical Club) in two parts, on April 27, and May 4, 1892.

In the first part, Freud dealt with the concepts of suggestion and hypnosis and, in the second, with the therapeutic role of hypnosis. The report, published in two instalments, is not equally divided between Freud's two themes; as will be seen, more than twice as much space was allocated to the second session.

Although Freud shows himself in this lecture to be most appreciative of the views of Bernheim and the Nancy school, several critical notes are struck in the later passages regarding both definition and practical application of suggestion.

Although manifestly second-hand, the report bears every mark of being an accurate presentation of Freud's original lecture, and since, in addition, the substance is of considerable interest and relevance, it has been thought worthwhile to include the present translation in the *RSE*.

REPORT OF A LECTURE 'ON HYPNOSIS AND SUGGESTION'

After a few introductory remarks on his personal relationship with the theme of the lecture, the speaker reminds us that the view of hypnotism as a tissue of fraud and self-deception, which held sway until recently, is now overcome, and that one can now assert that it deals with an important area of psychological fact of very close concern to the physician. He then states that the fundamental facts of hypnotism have been expressed in two different versions: by Charcot and by the men of the 'school of Nancy'. After a brief examination of Charcot's teachings, he turns to the conception [*Auffassung*][T] of the school of Nancy, for which he declares his unqualified support. First, he offers some interesting remarks on the personality of the founder of this school, Dr Liébeault, who devoted his life in the most selfless fashion to researching this problem, and also on Prof. Bernheim, whose publications directed general attention to the previously unnoticed doctrine and activity of Liébeault.

The school of Nancy defines *hypnosis* as a special psychical state in which *suggestibility* is increased. The speaker wishes now to use the first hour for a discussion of the concepts 'suggestion' and 'hypnosis', and he will go into the therapeutic role of hypnosis in a second lecture.

'Suggestion'[1] is defined by Bernheim as a psychical act whereby an idea is introduced into the brain of another person and accepted by him. However, this definition seems unsatisfactory because it is too broad. It permits of the conclusion that any psychical influence between two different people amounts to suggestion, and thus detracts from the characteristics of suggestion which are so striking in hypnosis. In fact, Bernheim is prepared to accept this implication and sees manifestations of suggestion in all psychical events. In response, the speaker seeks (by way of examples of injunction, persuasion, instruction, etc.) to establish the essential characteristics of suggestion, and comes to the

1 [The following outline of Bernheim's views, and the criticism of his definition of 'suggestion', echo passages in Freud's Preface to his translation of Bernheim's *Suggestion* (1888–89*a*) and in his review of Forel's *Hypnotism* (1889*a*); cf. pp. 81 ff. and 99 ff. above.]

conclusion that suggestion consists in the following: the brain accepts an idea presented to it from outside without exercising criticism upon it, although it has the material for such criticism at its disposal.

The major contribution of the school of Nancy is that it has tracked down the manifestations of suggestion in all areas of human mental life [*Seelenlebens*][T] and has demonstrated that we all prove to be suggestible under various conditions – a fact which demands far more wide-ranging interest than simply that of the physician. The speaker reported some highly remarkable experiments of Bernheim's, which demonstrated the totally unexpected degree of credulity in normal people.

Seele

Now, the physician is interested principally in knowing under what conditions people are suggestible. The following is an incomplete enumeration.

(1) Increased suggestibility manifests spontaneously as a permanently abnormal mental state – in a few cases.

(2) It occurs at times in affective states and under the influence of 'psychical infection'. Among the former, the state of religious faith is particularly noteworthy.

(3) It occurs in deep hypnosis, which is achieved by certain methods. The suggestibility of the hypnotic state is different in certain respects from suggestibility under other conditions. That is, hypnotic suggestion is generalized, whereas other forms of increased credulity are only achieved by suggestions which coincide with effective conditions. Thus a religiously suggestible person is only credulous in relation to suggestions which fit in with the content of his religious faith, but he is not gullible in general. He may accept on faith a miracle at Lourdes but would exercise sharp critical judgement if an attempt were made to give him illusory food. In hypnosis the suggestion is facilitated by the uniform weakening of all existing ideas; in religious faith, on the other hand, it is facilitated by intensification of a particular ideational group.

Another distinguishing feature of hypnotic suggestion is that it is associated with amnesia, which is absent in suggestibility under other conditions. However, the speaker himself tried to reduce the significance of this distinction by advancing the view that the amnesia of hypnosis merely stems from the fact that we avoid associating very different states of consciousness with one another. Thus, for example, we directly link the thought process of the morning with that of the previous evening, skipping out the night; and we notice every now and then that night after night we continue associations from a dream which began on the one night (of which we have no awareness by day) on the

following night. The amnesia of hypnosis is nothing more than one such avoidance of linking two different states of consciousness, for each successive hypnosis brings back the recollection of the previous one. Occasionally we are also amnesic under other circumstances – even at the height of affect, such as one can observe in violent tempers, when it is later disputed that ugly expressions were used.[1]

The speaker closed with the remark that it had hitherto been possible to keep the concepts 'hypnosis' and 'suggestion' separate from one another, but that this would now become more difficult. That is, when one studies the methods by which hypnosis is induced, it must be admitted that they themselves consist in the application of suggestion. If one adds, following the doctrines of the school of Nancy, that there are no regular physical signs in hypnosis, merely the character of increased suggestibility, then it can be understood how an insightful disciple of the Nancy school, Prof. Delboeuf, could express the proposition: 'There is no such thing as hypnosis, there are only varying types and degrees of suggestibility.'[2]

In the second lecture (on the therapeutic value of hypnosis and suggestion), which we would like to describe in more detail, Dr Freud said roughly the following.

Alongside the school of medicine which has endeavoured to base medical therapy upon the totality of prevailing natural-scientific knowledge – which has sought to advance the mathematical-physical or, as we say today, biological-chemical conception – there has always been a lay opposition: 'wild' medicine,[3] the principal characteristic of which was precisely that it left aside the scientific foundations of therapy. Such, in our time, are homoeopathy, the natural healer, the Pastor Kneipp,[4] etc. The successes of these lay therapies are, however, unquestionable and are not to be underestimated. If we ask ourselves what these successes consist in, it can well be said that not a single cure by such methods has ever occurred which is contradicted by our conclusions which are

1 [This 'state-dependent' theory of memory is elaborated further in the early drafts on hysteria (Sketch B, 1941*b* [1892], p. 177 f. below) and in Freud's neuroscientific article on amnesia (1893–94*a*), *NSW*, **4**. Cf. also an early reference to the defensive aspects of such processes in a footnote to Charcot's *Tuesday Lectures* (p. 166 below).]

2 [This is an allusion to Delboeuf's celebrated riposte to Bernheim's 'Tout est dans la suggestion', which Freud quoted in his case study of Frau Emmy von N. (1895*d*), *RSE*, **2**, 89. Cf. also p. 110 *n.* above.]

3 [Some quarter of a century later, when psychoanalysis had established its own orthodoxy, Freud was able to speak of a 'wild' analysis (Freud, 1910*k*; *RSE*, **11**, 213 ff.).]

4 [For details of Pastor Kneipp and his cure, see Freud (1898*a*), ibid., **3**, 267 and *n.* 3.]

based upon anatomy. Nobody whose *nervi ischiadici* [sciatic nerves] had sclerosed into tracts of glial connective tissue has yet been made to walk, nor to see if he did not possess a layer of rods and cones in his retinae. Here we are always concerned with cases which we [physicians] would also consider to be curable in principle, and which we too would succeed in curing in the course of time. Yet it is cause for thought that this wild medicine can make more or less the same discrimination [between curable and incurable cases] as we do in scientific medicine, and that it can even cure isolated cases which have proved resistant to rational therapy. It is therefore worthwhile to seek out the factor by which lay medicine achieves its results. On careful reflection it must be said that this can only be a psychical factor – for these cures are performed under three different conditions, in all of which the psychical factor of suggestion is unmistakable: (1) in places, visits to which are associated with increased religious faith – such as Lourdes, the place of prayer at Zeller on Lake Zürich, etc. – we have but recently come to recognize religious credulity as one of the most powerful influences capable to some extent of increasing suggestibility; (2) with methods of treatment which borrow their form from scientific medicine but which can only exert their effects by way of faith, for – according to our knowledge – they are entirely inadequate to the complaint at hand (indeed, homoeopathy belongs here); (3) those cases also belong here in which true rational therapy achieves effects which far exceed the actual powers of the therapy, because the suggestive influence which the physician exerts through the treatment joins in. Here the speaker cited the massage cures of Metzger, and referred for this interpretation to a lecture of Charcot's in which the suggestive effects exerted by Metzger were outlined.

In view of these experiences it seems justifiable that the physician should wish to master these suggestive factors so that he may utilize them in his therapeutic activity. The application of suggestion in hypnosis appears to be the most convenient procedure in this regard. The hope that the sphere of influence of rational therapy will be considerably broadened when it succeeds in placing the patient under deep hypnosis with amnesia (so-called somnambulism) is based not only upon the above experiences concerning the successes of lay therapy, but also upon a series of facts relating to the interaction of the physical and psychical in man. This theme is usually dealt with one-sidedly at [medical] school, where the psychical processes always appear to be dependent and derivative. The student learns of the somatic conditions for psychical functions, and of the influences exerted upon the latter by changes in blood supply

and by toxic substances or products. However, another series of facts, which are currently left in the background by the medical schools, show that the opposite is also true – that a most significant influence upon the bodily functions, effected by the psychical processes, also occurs.[1] What testifies to this, above all, are those bodily changes which play the most significant role in human relations – those collected together under the rubric of 'expressions of the emotions', which have achieved such great significance for our understanding of the neuroses, since increased expression of the emotions has come to be recognized as a typical characteristic of the *status nervosus*.[2] Furthermore, we know that all secretions can result from, and be inhibited by, ideas [*Vorstellungen*][T]. We know of examples of conspicuous trophic changes following primary changes in ideational life, and precisely in the example of neurasthenia it can be seen that it is now frequently necessary for one to assume that the psychical has an effect upon the physical, where we previously held the converse to be true. The speaker refers to reddening of the skin at specified places by inducing an idea under hypnosis as the most obvious phenomenon in this series – an experiment which he himself conducted repeatedly on a patient of Liébeault's – and he reports that even blisters and suppuration can be produced (in trustworthy men) in the same way.

Thus, if one has succeeded in inducing deep hypnosis, one can, by the induction of appropriate ideas: (1) remove all [symptomatic] manifestations, which themselves stem from ideas by resolutely contradicting these pathogenic ideas; and (2) also remove or inhibit other symptoms of disease of somatic origin – if the symptoms are not an inevitable expression of the course of that disease.

If the therapeutic application of hypnosis thus appears to be justified, then it is time to consider an objection – one which comes straight from those who well appreciate the therapeutic significance of suggestion. It is said that the physician should certainly use suggestion, but that he does so in any event, and always has. The physician constantly practises suggestion through his personality and through his comforting reassurances, and even our rational methods of treatment contain a bit of suggestion.[3] In every medical intervention the psychical factor of suggestion combines with the physical-chemical effects of the therapy.

1 An excellent collection of examples of this influence is contained in the well-known book by Hack Tuke [1872], *Influence of the Mind upon the Body*. [Similar remarks on the 'one-sidedness' of the medical schools were made by Freud (1905*b* [c. 1895/96]), *RSE*, **7**, 242 f.]

2 [Cf. the similar expression of Breuer's, who (without giving a specific reference) alludes to the theory of Oppenheim (1890) in *Studies on Hysteria* (1895*d*), *RSE*, **2**, 181, 185 and 218.]

3 [This point was already made in the Forel review (Freud, 1889*a*), p. 99 ff. above.]

It has just recently become questionable whether the efficacy of our electrotherapy does not for the most part rest upon suggestion.[1] Why, then, hypnosis as well? Autosuggestion is no different. It contributes nothing other than a new name. – One especially frequently hears this objection coming from outstanding physicians who enjoy great reputations, who, in fact, by mere communication with their patients – indeed, by their very mien – are capable of bringing the patient relief. To this objection one should reply that conscious suggestion is not generally practised by physicians, that they do not in general add anything to the autosuggestion of the patient. Suggestion occurs here and there, particularly with individual personalities, but the point is to make use of it deliberately, and on a large scale, and to make the therapeutic power of this factor quite generally available – even to those physicians who do not enjoy a special personal influence.

The speaker believes that it is only possible properly to consider this objection if one decides for or against Delboeuf: to describe hypnosis as a special state or as itself being only a product of suggestion. [Cf. p. 131 *n*. 2 above.] In the latter case it can justifiably be objected that hypnosis is not needed if what one achieves by it is no more than such an exercising of suggestion upon the patient as could also be brought about without hypnosis. Then it is also to be expected that hypnosis would lose its particular effects on patients if they realized that this state was incapable of exercising effects which are independent of their beliefs. In the other case – if hypnosis is a specific, physically definable state – it is clear that its use would represent a major advance in comparison with conventional suggestion on the part of physicians.

The speaker does not wish to go into this extremely important question here; he remarks only that, for his part, he still holds firmly to the conception of hypnosis as a specific state.[2] Hypnosis, by definition at least, is easily separated from the other states of increased suggestibility. Suggestion demonstrates quite generally that another person can be brought to adopt an idea on the basis of a psychological motive [*Motiv*][T] instead of a logical reason. This definition applies literally to the other forms of suggestion, but in hypnosis it occurs not because one provides the other person with a psychological motive but rather because the special psychical state removes the resistance to the new idea. One thing is certain, however: those who raise this objection can only find the

1 [Cf., in a slightly different connection, Freud's (1955*c* [1920]) 'Memorandum on the Electrical Treatment of War Neurotics', *RSE*, **17**, 207 ff.]

2 [Here Freud diverges from full support of the Nancy school.]

application of hypnosis to be unnecessary, not unacceptable. – The speaker now turns to the discussion of three questions: (1) What results does one in fact observe with the application of hypnosis? (2) What are the indications for its use? (3) What are the risks of, and objections to, its use?

(1) The results which one sees with the application of hypnosis in Bernheim's clinic and Liébeault's out-patient department are quite extraordinary, as the speaker verifies by means of examples. Also, the number of people in whom Bernheim induces somnambulism is unexpectedly high. For example, Bernheim hypnotizes ten out of twenty patients during a ward round, including not only long-stay patients but also those who were admitted one or two days previously. If one attempted to replicate this in one's private practice, one would have to be satisfied with a far more modest number of hypnoses. Bernheim himself – who is an absolutely honest researcher – reports that he does not achieve the same results in his private practice as he does with his hospital patients.[1] Apparently a number of factors combine to account for the successes in the clinic: Bernheim's unusual confidence, the personal influence always exerted by the physician in charge of a clinical department, the nature of the case material in a clinic, and the 'psychical infection' made possible there. In a word, what we are seeing with Bernheim is not so much the effects of hypnosis as of suggestion *per se*, similar to what occurs at Lourdes or with Pastor Kneipp and with individual famous physicians. In a private practice, where the physician is remunerated by patients who are educated, favourably disposed and come individually for treatment, all of these suggestive factors fall by the wayside. Now the results are dependent – not always, but on the whole – upon the depth of the hypnosis. One could therefore make it a rule to use hypnotic treatment in private practice only if one succeeds in inducing deep hypnosis. But then one would limit the use of this therapy too much, and individual instances where complete success was achieved despite bad hypnosis also militate against this rule.

One therefore decides to attempt suggestive therapy with incomplete or inadequate hypnosis. However, such efforts to induce suggestion where it does not naturally occur are a difficult and strenuous task for the physician – a sort of animal-taming which, in the long run, with all one's other commitments, one cannot endure. There are certainly people who possess great skill in this regard, but the difficulties of this

1 [This admission of Bernheim's was reported by Freud in his *Autobiographical Study* (1925*d*), *RSE*, **20**, 15. Cf. also the Editors' Introduction, p. 67 *n*. 1 above.]

psychological technique are so pronounced that one sees the justification for permitting the introduction of a specialization in the technique – such as is usually done according to the organs – and one would readily leave this kind of suggestive therapy to people who perform no other medical functions.[1] Without the amnesia which comes with deep hypnosis, the physician also forfeits his complete freedom in the use of suggestion – the requisite boldness in countering the manifestations of disease. He feels himself to be restrained involuntarily and unintentionally, for he knows that the patient experiences the full contradiction between reality and the claim contained in the suggestion, and that he will confront the physician with this on a later occasion.[2] Consequently, he becomes ever less confident, the results become ever more limited, and the inclination to continue the treatment becomes weaker on both sides – and soon repetition inevitably deprives the suggestive therapy of the cumulative effect which no other method does without.

The speaker can therefore not declare himself to be an 'enthusiastic adherent' of suggestive therapy when it is performed under such circumstances, in the absence of an effective suggestive milieu, without deep hypnosis. In any case, he considers this to be a question over which one can exercise judgement with objective composure. People in general are all too eager for something over which they can enthuse, that is, before which they can behave as if under suggestion, thus abrogating their sense of logic. Scientific truth is certainly one theme worthy of such enthusiasm, and Liébeault – for whom research into suggestion was a part of this truth – had a right to enthuse over it. Those who came after him, who received the finished doctrine, were no longer in this position; unprejudiced testing is all that was required, and it is as unworthy of a man of science to be an 'enthusiastic adherent' as it is for him to behave like a bitter opponent of suggestive therapy.

In the speaker's opinion, the case is different when it is possible for some reason to induce deep hypnosis with amnesia in all or most patients; this represents a broadening of our therapy, which could not have been thought out in a more meaningful way.

The speaker repeatedly emphasizes that the most important problem in the theory of hypnotism consists in the decision as to whether the state of hypnosis is a state characterized by special somatic and physical signs

1 [This seems to anticipate the development of psychoanalysis as a distinct profession; cf. Freud, 1926*e*; *RSE*, **20**.]

2 [Cf. some similar remarks by Charcot and by Freud on p. 168 below. Cf. also pp. 66–7 above. This whole section of Freud's lecture recalls his contribution to Bum's *Lexikon* (1891*d*) above.]

or, as Delboeuf claims, is a mere artefact of medical technique. All of the expectations which one might entertain for the future of hypnosis are linked to the resolution of this question. The fact that hypnosis can be induced by suggestion does not by any means decide the question. The speaker holds firmly to his opinion as to the genuineness of hypnosis, his arguments for which are drawn from the observation of hypnotic states in hysterics. On this important point he therefore approximates the views of the Charcot school. He could not, however, go more deeply into[1] this significant problem here.

[2] He turns to indications for the application of hypnotic therapy. Here things are arranged differently from how they are with other therapeutic indications. Indications are usually determined only by the pathological conditions. In hypnotic therapy the factor of the individuality of the patient comes into consideration to an exceptional degree. It is therefore difficult to say something general about this matter. In one patient, it is possible to suppress the symptoms of an illness which seem justified only by demonstrable anatomical changes. In another, a subjective symptom of decidedly psychical origin is resistant. As examples of the former, the speaker cited the case of a man in Bernheim's clinic suffering from Ménière's vertigo due to labyrinthine disease who was already unable to stand upright. He was able to walk almost normally four to five days after each hypnotic suggestion. After this period the effect diminished and had to be boosted by a new suggestion. In general, three categories of indications for hypnotic treatment may be advanced. (a) Cases with purely functional complaints, mostly of a nervous nature. (b) Cases of organic disease, in which the complaints are caused by a nervous intermediary. Here the speaker referred, by way of example, to the phenomenon of 'pain-blocking' [*Schmerzhemmung*][T], such as one observes in acute rheumatic fever. Bernheim has repeatedly demonstrated that a patient with acute inflammation of the joints can be induced by hypnosis to move the diseased limb (previously kept still) as if it were healthy, for several hours. (c) Cases of organic lesion in which the complaints are direct consequences of the lesion. In order to explain these sometimes mysterious results, one must here assume that the functional disturbance exceeds the bounds of the anatomical lesion, that the suggestion enlists other organs for compensatory purposes, etc.

Hemmung

Certain groups of patients (neurasthenics, for instance, and, on the whole, people with depressive disturbances of consciousness) are quite

1 ['*eingehen*.' Misprinted as '*entgehen*' ('escape from') in the German original; cf. *GW*, **Nachtr.**, 175 *n.* 2.]

unsuited to hypnotic treatment. This is regrettable, for it is in precisely these patients that one comes across most of the conditions which, by their nature, are suitable for hypnotic treatment. Yet one should not consider this [contra-indication] to be a general rule; every series of successful hypnotic treatments – like those of Bernheim himself, Wetterstrand,[1] etc. – contains a few examples of successful treatments of severe psychical neurasthenia. The relation of hysteria to hypnotic therapy is a special topic, which the speaker is excluding from the present discussion. However, his recognition of the existence of special relationships between hysteria and hypnotism means that, here again, he is approximating the teachings of Charcot. Hypnotic treatment offers the best results in normals, although they certainly do not need the treatment.

[3] In regard to the objections which have been levelled against hypnotic therapy, the speaker is of the view that they are all more or less correct, but nonetheless unfair, for they apply to an equal extent to all other therapies. The objection that the procedure does psychical damage to the patient comes from those physicians who have not carried out this procedure, whereas those who hypnotize a great deal have nothing to report regarding such dangers. Certainly with every therapy – and therefore with hypnosis too – one has to consider where and when to use it. We would have done considerable damage with an absolutely indispensable therapy – with the local treatment of gynaecological diseases – if we had applied it too frequently to unsuitable people, under certain personal conditions. The same can be observed with hypnosis, this being no reason to level accusations against it. The objection that hypnotic-suggestive therapy is merely a symptomatic treatment is, again, absolutely true, but this applies to the vast majority of our treatment methods. We possess only a very few causal therapies, are generally quite satisfied with symptomatic methods, and the patient expects nothing else from us. Incidentally, Bernheim – in a brilliant section of his new book on psychotherapy [1891][2] – has explained that, as a result of the interaction of symptoms with one another, symptomatic treatment does often enough contribute directly to cure. Hysteria, by the way, offers one instance where hypnosis permits of a truly causal treatment – but Freud wished to say no more about that here.[3]

1 [Otto Georg Wetterstrand (1845–1907), an influential Swedish hypnotist and co-founder of the *Zeitschrift für Hypnotismus* in Berlin.]

2 [Freud's translation of this book was published shortly after this report (Freud, 1892*a*).]

3 [Freud made similar remarks in the previous two papers (1889*a*, 1891*d*). He took the matter up in his writings on hysteria, starting with the following paper (1892–93*a*). See also Freud (1895*g*), *RSE*, **2**, 291 ff.]

A further reproach states that suggestive therapy achieves only temporary results, that at one time or another the patient relapses. This is untrue if it implies that relapses occur more readily after hypnotic therapy than with other treatments. That misimpression could arise in the following way. With other treatments, e.g. electrical therapy, one is prepared from the outset for an accumulation of the curative effects. One is not surprised if the neuralgia [for example] does not disappear after the first session; one applies more electricity until one has carried out the number of sessions which are felt to be sufficient. In a hypnotic treatment of the same neuralgia it can happen that the neuralgia disappears immediately upon suggestion. If it then returns the next day, one cannot call this a relapse; here, too, one must accumulate a sufficient number of suggestions in the treatment. Discounting this misunderstanding, relapse is not more common with hypnotic therapy than with any other form of therapy. Where it does occur, it arises from the nature of the case under treatment. It becomes a matter of whether one is dealing with a thriving neurotic process in which the causal factor is still active, or with cases in which the process has run its course and left only residual manifestations. In the former case, relapses occur no matter what therapy is used; in the other case, the residual manifestations will be definitively removed by hypnotic treatment. The speaker cites examples of this from his own medical experience.

The speaker concludes with an invitation to visit Bernheim's clinic in Nancy. He does not expect that we all would then become hypnotists – indeed, that would not be desirable – but the numerous important lessons which flow from the study of suggestion would not escape us, and from then on perhaps we should no longer judge so disapprovingly those colleagues who do practise hypnotic treatment.

A CASE OF SUCCESSFUL TREATMENT BY HYPNOTISM

(1892–93)

'A Case of Successful Treatment by Hypnotism'
1950 *CP*, **5**, 33–46. (Tr. James Strachey.)
1966 *SE*, **1**, 117–28. (Slightly corrected version of the 1950 translation.)

The present translation is a slightly revised version of the *SE* one.

This paper was almost exactly contemporaneous with the Breuer & Freud 'Preliminary Communication' (1893*a*), *RSE*, **2**. Some of the ideas in it (e.g. the 'counterwill') have a place in Freud's later work, and it forms something of a link between his writings on hypnotism and those on hysteria upon which he was embarking. The view that a 'moment of disposition to hysteria' – in this instance, physical fatigue – provides the opportunity for the counterwill to assert itself suggests the influence of Breuer and the 'hypnoid state'. (See p. 153 f. below.)

A CASE OF SUCCESSFUL TREATMENT BY HYPNOTISM

WITH SOME REMARKS ON THE ORIGIN OF HYSTERICAL SYMPTOMS THROUGH 'COUNTERWILL'

I propose in the following pages to publish an isolated case of a successful treatment by hypnotic suggestion because, owing to a number of attendant circumstances, it was more convincing and more lucid than the majority of our successful treatments. [117]

I have been acquainted for many years with the woman whom I was thus able to assist at an important moment of her existence, and she remained under my observation for several years afterwards. The disorder from which she was relieved by hypnotic suggestion had made its first appearance some time earlier. She had struggled against it in vain and been driven by it to a renunciation which, with my help, she was spared on a second occasion. A year later the same disorder appeared yet again, and was once more overcome in the same manner. The therapeutic success was of value to the patient and persisted as long as she desired to carry out the function affected by the disorder. Finally, it was possible in this case to trace the simple psychical mechanism of the disorder and to bring it into relation with similar happenings in the field of neuropathology.

It was a case, if I may now cease talking in riddles, of a mother who was unable to feed her newborn baby till hypnotic suggestion intervened, and whose experiences with an earlier and a later child provided controls of the therapeutic success such as are seldom obtainable.

The subject of the following case history is a young woman between twenty and thirty years of age with whom I happen to have been acquainted from her childhood. Her capability, her quiet common sense and her naturalness made it impossible for anyone, including her family doctor, to regard her as a neurotic. Taking the circumstances that I am about to narrate into account, I must describe her, in Charcot's happy phrase, as an *hystérique d'occasion*. This category, as we know, does not exclude the most admirable combination of qualities and otherwise uninterrupted nervous health. As regards her family, I am acquainted with her mother, who is not in any way neurotic, and a younger sister

[118] who is similarly healthy. A brother suffered from a typical neurasthenia of early manhood, and this ruined his career. I am familiar with the aetiology and course of this form of illness, which I come across repeatedly every year in my medical practice. Starting originally with a good constitution, the patient is haunted by the usual sexual difficulties at puberty; there follow years of overwork as a student, preparation for examinations, and an attack of gonorrhoea, followed by a sudden onset of dyspepsia accompanied by obstinate and inexplicable constipation. After some months the constipation is replaced by intracranial pressure, depression and incapacity for work.[1] Thenceforward the patient grows increasingly self-centred and his character more and more restricted, till he becomes a torment to his family. I am not certain whether it is not possible to *acquire* this form of neurasthenia with all its elements and therefore, especially as I am not acquainted with my patient's other relatives, I leave it an open question whether we are to assume the presence in her family of a hereditary disposition to neurosis.

When the time approached for the birth of the first child of her marriage (which was a happy one) the patient intended to feed the infant herself. The delivery was not more difficult than is usual with a primiparous mother who is no longer very youthful; it was terminated with forceps. Nevertheless, though her bodily build seemed favourable, she did not succeed in feeding the infant satisfactorily. There was a poor flow of milk, pains were brought on when the baby was put to the breast, the mother lost appetite and showed an alarming unwillingness to take nourishment, her nights were agitated and sleepless. At last, after a fortnight, in order to avoid any further risk to the mother and infant, the attempt was abandoned as a failure and the child was transferred to a wet-nurse. Thereupon all the mother's troubles immediately cleared up. I must add that I am not able to give a medical or eye-witness account of this first attempt at lactation.

Three years later a second baby was born; and on this occasion external circumstances added to the desirability of avoiding a wet-nurse. But the mother's attempts at feeding the child herself seemed even less successful and to provoke even more distressing symptoms than the first time. She vomited all her food, became agitated when it was brought to her bedside and was completely unable to sleep. She became so much
[119] depressed at her incapacity that her two family doctors – physicians of such wide repute in Vienna as Dr Breuer and Dr Lott – would not hear of

1 [These include symptoms by which Freud was later to distinguish neurasthenia proper from anxiety neurosis. Cf. his first paper on anxiety neurosis (1895*b*), *RSE*, **3**, 81 ff.]

any prolonged attempt being made on this occasion. They recommended that just one more effort should be made – with the help of hypnotic suggestion; and, on the evening of the fourth day, they saw to it that I was brought in professionally, since I was already personally acquainted with the patient.

I found her lying in bed with flushed cheeks and furious at her inability to feed the baby – an inability which increased at every attempt but against which she struggled with all her strength. In order to avoid the vomiting, she had taken no nourishment the whole day. Her epigastrium was distended and was sensitive to pressure; palpation revealed abnormal motility of the stomach; there was odourless eructation from time to time and the patient complained of having a constant bad taste in her mouth. The area of gastric resonance was considerably increased. Far from being welcomed as a saviour in the hour of need, I was obviously being received with a bad grace and I could not count on the patient's having much confidence in me.

I at once attempted to induce hypnosis by ocular fixation, at the same time making constant suggestions of the symptoms of sleep. After three minutes the patient was lying back with the peaceful expression of someone in profound sleep. I cannot recollect whether I made any tests for catalepsy and other symptoms of pliancy. I made use of suggestion to contradict all her fears and the feelings on which those fears were based: 'Have no fear [*Angst*][T]! You will make an excellent nurse and the baby will thrive. Your stomach is perfectly quiet, your appetite is excellent, you are looking forward to your next meal, etc.' The patient went on sleeping while I left her for a few minutes, and when I had woken her up showed amnesia for what had occurred. Before I left the house I was also under the necessity of contradicting a worried remark by the patient's husband to the effect that a woman's nerves might be totally ruined by hypnosis.

Next evening I was told something which seemed to me a guarantee of success but which, oddly enough, had made no impression on the patient or her relations. She had had a meal the evening before without any ill effects, had slept peacefully and in the morning had taken nourishment herself and fed the baby irreproachably. The rather abundant midday meal, however, had been too much for her. No sooner had it been brought in than her former disinclination returned: vomiting began even before she had touched it. It was impossible to put the child to her [120]
breast and all the objective signs were the same as they had been when I had arrived the evening before. I produced no effect by my argument that, since she was now convinced that her disorder *could* disappear and

in fact *had* disappeared for half a day, the battle was already won. I now brought on the second hypnosis, which led to a state of somnambulism as quickly as the first, and I acted with greater energy and confidence. I told the patient that five minutes after my departure she would break out against her family with some acrimony: what had happened to her dinner? Did they mean to let her starve? How could she feed the baby if she had nothing to eat herself? And so on.

When I returned on the third evening the patient refused to have any further treatment. There was nothing more wrong with her, she said: she had an excellent appetite and plenty of milk for the baby, there was not the slightest difficulty when it was put to her breast, and so on. Her husband thought it rather peculiar that after my departure the evening before she had clamoured violently for food and had remonstrated with her mother in a way quite unlike herself. But since then, he added, everything had gone all right.

There was nothing more for me to do. The mother fed her child for eight months; and I had many opportunities of satisfying myself in a friendly way that they were both doing well. I found it hard to understand, however, as well as annoying, that no reference was ever made to my remarkable achievement.

But my time came a year later, when a third child made the same demands on the mother and she was as unable to meet them as on the previous occasions. I found the patient in the same condition as the year before and positively exasperated with herself because her will could do nothing against her disinclination for food and her other symptoms; and the first evening's hypnosis only had the result of making her feel more hopeless. Once again after the second hypnosis the symptoms were so completely cut short that a third was not required. This child too, which is now eighteen months old, was fed without any trouble and the mother has enjoyed uninterrupted good health.

In face of this renewed success the patient and her husband unbent and admitted the motive that had governed their behaviour towards me. 'I felt ashamed', the woman said to me, 'that a thing like hypnosis should be successful where I myself, with all my willpower, was helpless.' [121] Nevertheless, I do not think either she or her husband have overcome their dislike of hypnosis.

I shall now pass on to consider what may have been the psychical mechanism of this disorder of my patient's which was thus removed by suggestion. I have not, as in certain other cases which I shall discuss

elsewhere,[1] direct information on the subject; and I am thrown back upon the alternative of deducing it.

There are certain ideas [*Vorstellungen*][T] which have an affect of expectancy attached to them. They are of two kinds: ideas of my doing this or that – what we call *intentions* – and ideas of this or that happening to me – *expectations* properly speaking. The affect attached to them is dependent on two factors, first on the degree of importance which the outcome has for me, and second on the degree of uncertainty inherent in the expectation of that outcome. The subjective uncertainty, the counter-expectation, is itself represented by a collection of ideas to which I shall give the name of 'distressing antithetic ideas' [*Kontrastvorstellungen*]. In the case of an intention, these antithetic ideas will run: 'I shall not succeed in carrying out my intention because this or that is too difficult for me and I am unfit to do it; I know, too, that certain other people have also failed in a similar situation.' The other case, that of an expectation, needs no comment: the counter-expectation consists in enumerating all the things that could possibly happen to me other than the one I desire. Further along this line we should reach the *phobias*, which play so great a part in the symptomatology of the neuroses. But let us return to the first category, the intentions. How does a person with a healthy ideational life deal with antithetic ideas against an intention? With the powerful self-confidence of health, he suppresses and inhibits [*hemmt*][T] them so far as possible, and excludes them from his associations [*Assoziation*][T]. This often succeeds to such an extent that the existence of an antithetic idea against an intention is as a rule not manifest, but is only made probable when we come to consider the neuroses. On the other hand, where a neurosis is present – and I am explicitly referring not to hysteria alone but to the *status nervosus* in general – we have to assume the *primary presence* of a tendency to depression and to a lowering of self-confidence, such as we find very highly developed and in isolation in melancholia. In neuroses, then, great attention is paid [by the patient] to antithetic ideas against intentions, perhaps because the subject matter of such ideas fits in with the mood of the neurosis, or perhaps because antithetic ideas, which would otherwise have been absent, flourish in the soil of a neurosis. [122]

Hemmung

When this intensification of antithetic ideas relates to *expectations*, if the case is one of a simple *status nervosus*, the effect is shown in a generally pessimistic frame of mind; if the case is one of neurasthenia, associations with the most accidental sensations occasion the numerous

1 [A reference to the Breuer & Freud 'Preliminary Communication' (1893*a*) which was on the point of appearing.]

phobias of neurasthenics. When the intensification attaches to *intentions*, it gives rise to the disturbances which are summed up under the description of *folie du doute*, and which have as their subject matter distrust of the subject's own capacity. Precisely at this point the two major neuroses, neurasthenia and hysteria, each behave in a different manner, characteristic of each. In neurasthenia the pathologically intensified antithetic idea is combined with the volitional idea [*Willensvorstellung*] into a *single* act of consciousness; it subtracts from the volitional idea and brings about the weakness of will which is so striking in neurasthenics and of which they themselves are aware. The process in hysteria differs from this in two respects, or possibly only in one. [Firstly,] in accordance with the tendency to a *dissociation of consciousness* in hysteria, the distressing antithetic idea, which seems to be inhibited, is removed from association with the intention and continues to exist as a disconnected idea, often unconsciously to the patient himself. [Secondly,] it is supremely characteristic of hysteria that, when it comes to the carrying out of the intention, the inhibited antithetic idea can put itself into effect[1] by innervation of the body just as easily as does a volitional idea in normal circumstances. The antithetic idea establishes itself, so to speak, as a '*counterwill*', while the patient is aware with astonishment of having a will which is resolute but powerless. Perhaps, as I have said, these two factors are at bottom one and the same: it may be that the antithetic idea is only able to put itself into effect because it is not inhibited by being combined with the intention in the way in which the intention is inhibited by it.[2]

If in our present case the mother who was prevented by neurotic difficulties from feeding her child had been a neurasthenic, her behaviour
[123] would have been different. She would have felt conscious dread of the task before her, she would have been greatly concerned with the various possible accidents and dangers and, after much temporizing with anxieties and doubts, would after all have carried out the feeding without any difficulty; or, if the antithetic idea had gained the upper hand, she would have abandoned the task because she felt afraid of it. But the hysteric behaves quite otherwise. She may perhaps not be conscious of her fear, she is quite determined to carry her intention through and sets about it without hesitating. Then, however, she behaves as though it was her will

1 ['*Sich objektiviert*', literally 'makes itself objective'. In his own abstract of this paper (Freud, 1897*b*), Freud uses the word '*Realisierung*', 'making real' (*RSE*, **3**, 242).]

2 In the interval between writing this and correcting the proofs, I have come across a work by H. Kaan (1893) containing similar arguments.

not to feed the child on any account. Moreover, this will evokes in her all the subjective symptoms which a malingerer would put forward as an excuse for not feeding her child: loss of appetite, aversion to food, pains when the child is put to her breast. And, since the counterwill exercises greater control over the body than does conscious simulation, it also produces a number of objective signs in the digestive tract which malingering would be unable to bring about. Here, in contrast to the *weakness* of will shown in neurasthenia, we have a *perversion* of will; and, in contrast to the resigned irresoluteness shown in the former case, here we have astonishment and exasperation at a disunity which is incomprehensible to the patient.

I therefore consider that I am justified in describing my patient as an *hystérique d'occasion*, since she was able, as a result of a fortuitous cause, to produce a complex of symptoms with a mechanism so supremely characteristic of hysteria. It may be assumed that in this instance the fortuitous cause was the patient's excited state before the first confinement or her exhaustion after it. A first confinement is, after all, the greatest shock to which the female organism is subject, and as a result of it a woman will as a rule produce any neurotic symptoms that may be latent to her disposition.

It seems probable that the case of this patient is a typical one and throws light upon a large number of other cases in which breast-feeding or some similar function is prevented by neurotic influences. Since, however, in the case I have reported I have only arrived at the psychical mechanism by inference, I hasten to add an assurance that I have frequently been able to establish the operation of a similar psychical mechanism in hysterical symptoms *directly*, by investigating the patient under hypnosis.[1]

Here I will mention only one of the most striking instances.[2] Some [124]
years ago I treated a hysterical lady who showed great strength of will in those of her dealings which were unaffected by her illness; but in those which *were* so affected she showed no less clearly the weight of the burden imposed on her by her numerous and oppressive hysterical impediments and incapacities. One of her striking characteristics was a peculiar noise which intruded, like a tic, into her conversation. I can best

1 See the 'Preliminary Communication' by J. Breuer & S. Freud [1893*a*] on 'The Psychical Mechanism of Hysterical Phenomena', which is appearing at the same time as the present paper.

2 [This patient, Frau Emmy von N., was subsequently made the subject of the second case history in Breuer & Freud's *Studies on Hysteria* (1895*d*). See especially *RSE*, **2**, 45, 49 f., 52–3 and 81–2. Her case is also referred to briefly in the 'Preliminary Communication', ibid., **2**, 4–5. The accounts differ in their details.]

describe it as a singular clacking of the tongue with a sudden interruption of the convulsive closure of her lips. After observing it for some weeks, I once asked her when and how it had first originated. 'I don't know when it was,' she replied, 'oh! a long time ago.' This led me to regard it as a genuine tic, till it occurred to me one day to ask the patient the same question under deep hypnosis. This patient had access under hypnosis (without there being any necessity to suggest the idea to her) to the whole store of her memories – or, as I should prefer to put it, to the whole extent of her consciousness, which was restricted in her waking life. She promptly answered: 'It was when my younger girl was so ill and had been having convulsions all day but had fallen asleep at last in the evening. I was sitting beside her bed and thought to myself: "Now you must be absolutely quiet, so as not to wake her." It was then that the clacking came on for the first time. Afterwards it passed off. But once, some years later, when we were driving through the forest near ——, a violent thunderstorm came on and a tree-trunk beside the road just in front of us was struck by lightning, so that the coachman had to rein in the horses suddenly, and I thought to myself: "Now, whatever you do, you mustn't scream, or the horses will bolt." And at that moment it came on again, and has persisted ever since.' I was able to convince myself that the noise she made was not a genuine tic, since, from the moment it was in this way traced back to its origin, it disappeared and never returned during all the years I remained in contact with the patient. This, however, was the first occasion on which I was able to observe the origin of hysterical symptoms through the putting into effect of a distressing antithetic idea – that is, through counterwill. The mother, worn out by anxieties and her duties as a nurse, made a decision not to let a sound
[125] pass her lips for fear of disturbing her child's sleep, which had been so long in coming. But in her exhausted state the attendant antithetic idea that she nevertheless *would* do it proved to be the stronger; it made its way to the innervation of the tongue, which her decision to remain silent may perhaps have forgotten to inhibit, broke through the closure of her lips and produced a noise which thenceforward remained fixated[1] for many years, especially after the same course of events had been repeated.

1 ['*Fixiert*.' Is this word used in its everyday sense of 'fixed'? Or is it used in the more technical sense of 'fixated'? The question is a constant plague to the translator at this period. Freud uses the word in a variety of ways. We have already come across '*Fixierung*' in quite another sense, as used by hypnotists, to mean 'a concentrated stare'. (See the Preface to the Bernheim translation (1888–89*a*), pp. 86–7 above, the review of Forel (1889*a*), p. 104 above, and the encyclopaedia article on 'Hypnosis' (1891*d*), p. 118 above.) Leaving this special sense on one side, we come to a number of cases, such as the present one, in which the word is used in something that approaches the ordinary sense of 'permanently set' or 'established'. See, for instance, the early lecture on the 'Preliminary Communication' (1893*h*), *RSE*, **3**, 31, where, as here, a symptom becomes 'fixated'; or the French paper on motor paralyses (1893*c*), p. 199 below, where an idea is 'fixated' to a memory;

There is one objection that must be met before we can fully understand this process. It may be asked how it comes about that it is the *antithetic* idea that gains the upper hand as a result of general exhaustion (which is what constitutes the disposition for the process). I should reply by putting forward the theory that the exhaustion is in fact only a *partial* [126] one. What are exhausted are those elements of the nervous system which form the material foundation of the ideas associated with the primary consciousness; the ideas that are excluded from that chain of associations – that is, from the chain of associations of the normal ego [*Ichs*][T] – the inhibited and suppressed ideas, are *not* exhausted, and they consequently predominate at the moment of disposition to hysteria.

Anyone who is well acquainted with hysteria will observe that the psychical mechanism which I have been describing offers an explanation not merely of isolated hysterical occurrences but of major portions of the old symptomatology of hysteria as well as of one of its most striking characteristics. If we keep firmly in mind the fact that it is the distressing antithetic ideas (inhibited and rejected by normal consciousness) which press forward at the moment of disposition to hysteria and find their way to the somatic innervation, we shall then hold the key to an understanding of the peculiarity of the deliria of hysterical attacks as well. It is owing to no chance coincidence that the hysterical deliria of nuns during the epidemics of the Middle Ages took the form of violent blasphemies and unbridled erotic language or that (as Charcot remarked in the first volume of his *Leçons du mardi*) it is precisely well-brought-up and well-behaved boys who suffer from hysterical attacks in which they give free play to every kind of rowdiness, every kind of wild escapade and bad conduct.[1] It is the suppressed – the laboriously suppressed – groups of

or, another instance of a symptom being 'fixated', the second paper on the neuropsychoses of defence (1896*b*), *RSE*, **3**, 183. A more doubtful case can be seen in Draft L of the Fliess papers, dating from 1897 (p. 276 below); but an instance in the 'Dora' case history (1905*e* [1901]), *RSE*, **7**, 51, and several in the *Three Essays* (1905*d*) – especially ibid., **7**, 208 – show that the final psychoanalytic sense of a developmental stoppage has been reached. It should be noted that in this psychoanalytic sense the word still has two uses – fixation of a drive to an object and fixation of a drive at some particular point in its development. These two uses correspond to the two kinds of temporal regression which are described below in Appendix A to the 'Project' (p. 369 f.). Indeed, as is shown (with references) in the same passage, there is the closest clinical connection between fixation and regression in these senses. Finally, mention must be made of the very exceptional occurrence of the word '*Fixierung*' in the sense of 'record' or 'recording'. It appears thus in Chapter VII (B) of *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 481 f., but thereafter not, it seems, till *Moses and Monotheism* (1939*a*), ibid., **23**, 57, and *An Outline of Psychoanalysis* (1940*a* [1938]), ibid., **23**, 145. In all these last passages we have translated the word 'record'. (Cf. also Letter 52 to Fliess, p. 261 *n.* 3 below.)]

1 [The nuns and well-behaved boys appear several times at this period, e.g. in the 'Preliminary Communication' (1893*a*), *RSE*, **2**, 10, in Breuer's theoretical section of *Studies on Hysteria*, ibid., **2**, 222, in Freud's early lecture on hysteria (1893*b*), ibid., **3**, 36–7, as well as in one of his footnotes to his translation of Charcot's *Leçons du mardi* (1892–94*a*), p. 166 below, and again on p. 181.]

ideas that are brought into action in these cases, by the operation of a sort of counterwill, when the subject has fallen victim to hysterical exhaustion. Perhaps, indeed, the connection may be a more intimate one, for the hysterical condition may perhaps be *produced* by the laborious suppression; but in the present paper I have not been considering the psychological features of that condition. Here I am merely concerned with explaining why – assuming that there is a state of disposition to hysteria – the symptoms take the particular form in which we in fact observe them.

This emergence of a counterwill is chiefly responsible for the demonic characteristic which hysteria so often exhibits – the characteristic, that
[127] is, of the patients' not being able to do something precisely when and where they want to most passionately, of doing the exact opposite of what they have been asked to do, and of being obliged to cover everything they most value with abuse and suspicion. The perversity of character shown by hysterical patients, their itch to do the wrong thing, to appear to be ill just when they most want to be well – compulsions [*Zwang*][T] such as these (as anyone who has had to do with these patients will know) may often affect the most irreproachable characters when for a time they become the helpless victims of their antithetic ideas.

The question of what becomes of inhibited intentions seems to be meaningless in regard to normal ideational life. We might be tempted to reply that they simply do not occur. The study of hysteria shows that nevertheless they *do* occur, that is to say that the physical alteration corresponding to them is retained, and that they are stored up and enjoy an unsuspected existence in a sort of shadow kingdom, till they emerge like bad spirits and take control of the body, which is as a rule under the orders of the predominant ego consciousness.

I have already said that this mechanism is supremely characteristic of hysteria; but I must add that it does not occur only in hysteria. It is present in striking fashion in *tic convulsif*, a neurosis which has so much symptomatic similarity with hysteria that its whole picture may occur as a part-manifestation of hysteria. So it is that Charcot, if I have not completely misunderstood his teachings on the subject, after keeping the two separate for some time, could find only one distinguishing mark between them – that hysterical tic disappears sooner or later, while genuine tic persists. The picture of a severe *tic convulsif* is, as we know, made up of involuntary movements frequently (according to Charcot and Guinon, always) in the nature of

grimaces or of performances which have at one time had a meaning – of coprolalia, of echolalia and of obsessive ideas [*Zwangsvorstellungen*] belonging to the range covered by *folie du doute*. It is, however, surprising to learn that Guinon, who had no notion whatever of entering into the psychical mechanism of these symptoms, tells us that some of his patients arrived at their spasms and grimaces because an antithetic idea had put itself into effect. These patients reported that on some particular occasion they had seen a similar tic, or a comedian intentionally making a similar grimace, and felt afraid that they might be obliged to imitate the ugly movements. Thenceforward they had actually begun imitating them. No doubt only a small proportion of the involuntary movements occurring in tics originate in this way. On the other hand, it would be tempting to attribute to this mechanism the origin of coprolalia, a [128] term used to describe the involuntary or, rather, the unwilling ejaculation of the foulest words, which occurs in tics. If so, the root of coprolalia would be the patient's perception that he cannot prevent himself from producing some particular sound, usually a 'h'm h'm'. He would then become afraid of losing control over other sounds as well, especially over words such as any well-brought-up man avoids using, and this fear would lead to what he feared coming true. No anamnesis confirming this suspicion is quoted by Guinon, and I myself have never had occasion to question a patient suffering from coprolalia. On the other hand, I have found in the same writer's work a report upon another case of tic in which the word that was involuntarily spoken did not, exceptionally enough, belong to the coprolalic vocabulary. This was the case of an adult man who was afflicted with the necessity of calling out 'Maria!' When he was a schoolboy he had had a sentimental attachment to a girl of that name; he had been completely absorbed in her, and this, it may be supposed, predisposed him to a neurosis. He began at that time to call out his idol's name in the middle of his school classes, and the name persisted with him as a tic half a lifetime after he had got over his love affair. I think the explanation must be that his most determined endeavour to keep the name secret was reversed, at a moment of special excitement, into the counterwill and that thereafter the tic persisted as it did in the case of my second patient. If my explanation of this instance is correct, it would be tempting to derive

coprolalic tic proper from the same mechanism, since obscene words are secrets that we all know and the knowledge of which we always try to conceal from one another.[1]

1 I will merely add a suggestion that it would be rewarding to study elsewhere than in hysteria and tic the way in which the counterwill puts itself into effect – an event which very frequently occurs within the limits of the normal. [This is an anticipation of *The Psychopathology of Everyday Life* (1901*b*), where, almost ten years later than this paper, the 'counterwill' reappears (*RSE*, **6**, 134 and 236). It occurs once more, also in connection with parapraxes, in Lecture IV of the *Introductory Lectures* (1916–17*a*), ibid., **15**, 63 ff.]

PREFACE AND FOOTNOTES TO THE TRANSLATION OF CHARCOT'S *TUESDAY LECTURES* (1892–94)

EDITORS' NOTE

PREFACE AND FOOTNOTES TO THE TRANSLATION OF CHARCOT'S *LEÇONS DU MARDI À LA SALPÊTRIÈRE (1887–8)*

ENGLISH TRANSLATION

1966 *SE*, **1**, 133–43. (Tr. James Strachey.)

The present translation is a revised reprint of the *SE* one. The French volume was published in Paris in 1888.

The date of publication of Freud's translation raises some rather doubtful questions of chronology. His Preface is dated 'June, 1892' and the title page in some bound copies of the book is also dated '1892'; but other copies of the title page are dated '1894'. The book was in fact issued in instalments over these years. Freud enclosed one instalment (probably the first) in a letter to Fliess dated June 28, 1892, with this comment: 'The instalment of Charcot which I send you today is on the whole successful; but it annoys me, owing to several uncorrected wrong accents and spelling mistakes in the few French words. Slipshod!'[1]

The method of publication in instalments leads to some inconsistencies in Freud's footnotes. For instance, there are two references in them to his paper on the distinction between organic and hysterical paralyses (1893*c*, included in the present volume, p. 187 ff. below), one before (see p. 168) and one after (p. 169) the paper's publication, which in fact took place late in July, 1893. Similarly, there are two references to the Breuer & Freud theory of hysteria, one almost certainly before (see p. 166) and one after (p. 169) the publication of the 'Preliminary Communication' (1893*a*), which occurred at the beginning of January, 1893. The earlier of these hints at the theory of

1 In a letter to Fliess dated May 21, 1894, Freud mentioned that he was engaged on the last instalment of the *Leçons du mardi*.

[132] catharsis may possibly be its very first publication;[1] but unluckily we have no material to establish the exact date of the instalment concerned.

The number of footnotes which Freud added to this translation is very large, and many of them are sharply critical of Charcot's opinions. In *The Psychopathology of Everyday Life* (1901*b*), Freud mentions the matter a little apologetically: 'I added notes to the text which I translated, without asking the author's permission, and some years later I had reason to suspect that the author was displeased with my arbitrary action' (*RSE*, **6**, 139). The footnotes are largely concerned with purely neurological topics, and we have included here only those which are of psychological interest. For the others, see *NSW*, **4**.

It may be remarked, finally, that Charcot himself died (in the summer of 1893) before the publication was finished.[2]

1 See, however, the Villaret article on hysteria, p. 42 above.

2 The second volume of the German translation was produced not by Freud but by Dr Max Kahane (see p. 80 above), in 1895.

PREFACE TO THE TRANSLATION OF CHARCOT'S *TUESDAY LECTURES*

The lectures by Charcot, which are here translated into German with the author's kind permission, bear in French the title *Leçons du mardi à la Salpêtrière*. This title is derived from the day of the week on which the Professor on duty deals in person before his audience with the patients in the out-patient department. The first volume of these *Leçons* appeared in 1888 in a very modest form as 'Notes by MM. Blin, Charcot junior and Colin'. In the present year (1892) it was revised by the author; and this revision is the basis of our German edition. [133]

The French edition was introduced by a preface by Dr Babinski,[1] in which that preferred pupil of Charcot insists with just pride on how an almost inexhaustible abundance of stimulation and instruction has sprung from the 'Master' for many years past, and on how imperfectly the study of his published writings can replace his oral teaching. He therefore believes the plan justified of further bringing before the public these improvised lectures of Charcot and in that way of immeasurably widening the circle of his pupils and of his audience. And no-one, I think, who has had the good fortune even for a short time to see the great discoverer at work and to assimilate his teachings will fail to agree heartily with Dr Babinski.

These lectures in fact contain so much that is novel that there is nobody, not even among experts, who will read them without a substantial increase of his knowledge. But this novelty is given such a stimulating and impressive shape that it is qualified, as perhaps no other work since Trousseau's *Leçons*,[2] to serve as a textbook for students and for any physician wishing to maintain his interest in neuropathology.

1 [Joseph-François Babinski (1857–1932). Although Babinski was Charcot's 'preferred pupil' at the time that Freud wrote this Preface, he was later severely critical of his master's work. A short review by Freud of a paper by Babinski can be found among his neuroscientific writings (Freud, 1892*e*; *NSW*, **1**).]

2 [Armand Trousseau (1801–67), a French physician whose *Traité de thérapeutique* (with Pidoux, 1836, 1839) was long a classic.]

These lectures owe a peculiar charm to the fact that they are entirely, or for the most part, improvisations. The Professor does not know the patient who is brought before him, or knows him only superficially. He is obliged to behave before his audience as he ordinarily does only in his medical practice, with the exception that he thinks aloud and allows his audience to take part in the course of his conjectures and investigations.
[134] He questions the patient, examines one symptom or another, and in that way determines the diagnosis of the case and restricts it or confirms it by further examination. We observe that he has compared the case before him with a collection of clinical pictures derived from his experience and stored in his memory, and has identified the appearance of the present case with one of these pictures. This too is indeed the way in which we all arrive at a diagnosis beside a sick-bed, even though official clinical teaching sometimes gives the student a different idea. This is followed by differential diagnostic comments, and the lecturer endeavours to make clear the grounds on which his identification was based: grounds which, as we know, some good diagnosticians are unable to formulate, though they have their judgement determined by them. The further discussion relates to the clinical peculiarity of the case. The clinical picture, the '*entité morbide*', remains the basis of the whole study; but the clinical picture consists in a series of phenomena, a series which often branch off in a number of directions. The clinical assessment of the case lies in assigning it its place in this series. In the centre of the series lies the '*type*', the consciously and intentionally schematized extreme form of the clinical picture; or several such types can be set up, which are connected by transitional forms. It is certainly true that the '*type*', the complete and characteristic portrayal of the clinical picture, *can* be met with; but the cases that are actually observed diverge as a rule from the type: one or another of the picture's traits is obliterated; they can be arranged in one or more series departing from the type and end at last in quite indeterminate, rudimentary forms (*formes frustes*[1]), in which only the expert can still recognize derivatives of the type. While the description of clinical pictures is the subject matter of nosography, the task of clinical medicine is to follow out the individual form taken by cases and the combination of their symptoms.

I have laid emphasis here on the concepts of the '*entité morbide*', of the series, of the '*type*' and of the '*formes frustes*' because it is in their employment that a main characteristic of the French method of clinical practice resides. This way of looking at things is in fact foreign to the

1 [The French word '*fruste*' applied originally to 'effaced' coins or medals.]

German method. In the case of the latter the clinical picture and the type play no principal part; on the other hand, another characteristic comes into prominence, which is explained by the evolution of German clinicians: a tendency to make a physiological interpretation of the clinical [135]
condition and of the interrelation of the symptoms. The clinical observation of the French undoubtedly gains in self-sufficiency in that it relegates physiological considerations to a second place. Their removal, however, may be the chief explanation of the puzzling impression made by the French clinical methods on the uninitiated. In this, incidentally, there is no neglect, but a deliberate exclusion which is considered expedient. I have heard Charcot say: 'Je fais la morphologie pathologique, je fais même un peu l'anatomie pathologique; mais je ne fais pas la physiologie pathologique, j'attend que quelq'un autre la fasse.'[1]

Our appreciation of these lectures would be lamentably incomplete if it were to be broken off at this point. Interest in a lecture was often properly aroused only when the diagnosis had been made and the case had been dealt with in accordance with its peculiarities. After this, Charcot would take advantage of the freedom afforded by this method of instruction in order to make what we had seen into the starting point for remarks on similar cases in his recollection and for introducing the most important discussions on the genuinely clinical topics of their aetiology, heredity and connection with other illnesses. It was then that – spellbound by the narrator's artistry no less than by the observer's penetration – we listened to the little stories which showed how a medical experience had led to a new discovery; it was then that, along with our teacher, we were carried up from the consideration of a clinical picture in nervous disease to a discussion of some fundamental problem of disease in general; it was then, too, that all at once we saw the teacher and the physician give place to the sage, whose open mind has absorbed the great and motley picture of the world's workings, and who gives us a glimpse of how nervous diseases are not to be looked on as a whim of pathology but as a necessary component of the whole aggregation. These lectures present so accurate a picture of Charcot's manner of speaking and thinking that, for anyone who has once sat among his audience, the

1 ['I practise pathological morphology, I even practise a little pathological anatomy; but I do not practise pathological physiology. I expect someone else to do it.' – It may be remarked that Freud himself followed the French method to a large extent, at all events in his earlier nosographic work. See in particular his first paper on anxiety neurosis (1895*b*). The advantage of the French method over the German one for the study of neuroses, the physiology of which was completely unknown, is obvious. For a full discussion of this, see Solms (2000*a*). The present account of Charcot's way of working appears in a summary form in Freud's obituary of him, written some eighteen months later (1893*f*), *NSW*, **4**; *RSE*, **3**, 12.]

memory of the Master's voice and looks comes alive once more and the
[136] precious hours return in which the magic of a great personality bound his hearer irrevocably to the interests and problems of neuropathology.

I must add a few words to justify the notes which, printed in smaller type, interrupt the flow of Charcot's exposition at very irregular intervals. These originate from me and consist in part of explanations of the text and additional references to the literature, but in part of critical objections and glosses such as might occur to a member of the audience. I hope these remarks will not be understood as though I were trying in any way to set my views above those of my honoured teacher, to whom I am also under a personal obligation as a pupil. I am merely claiming, rather, the right to criticize which is used, for instance, by every reviewer in a technical journal irrespective of his own merits. There are so many things in neuropathology that are still unexplained and debatable and an understanding of which can only benefit from ventilation, that I have ventured to enter into discussion of a few of these points which are touched on in the lectures. I do so, naturally enough, from my own point of view insofar as this differs from the theories of the Salpêtrière. Charcot's readers, however, have no occasion to pay more attention to my remarks in this connection than these might otherwise deserve on their own account.

In my rendering of these lectures it has been my endeavour, not indeed to imitate Charcot's incomparably clear and at the same time elevated style – which would have been unattainable for me – but to blur as little as possible their characteristically informal language.

DR SIGM. FREUD
Vienna, June, 1892

EXTRACTS FROM FREUD'S FOOTNOTES TO HIS TRANSLATION OF CHARCOT'S *TUESDAY LECTURES*

P. 107 [Charcot had been giving an account of hysterical attacks.] [137]

. . . I avail myself of the opportunity offered in the text in order to lay before the reader an independent view of hysterical attacks. Charcot's 'type', with its modifications and the possibility of each stage becoming independent and representing the whole attack, etc., is undoubtedly extensive enough to cover all the observed forms of attack. For that very reason it will perhaps be argued in some quarters that it does not represent a true entity.

I have attempted to meet the problem of hysterical attacks along a line other than descriptive, and by examining hysterical patients in a hypnotic state I have arrived at new findings, a few of which I will mention here. The core of a hysterical attack, in whatever form it may appear, is a *memory*, the hallucinatory reliving of a scene which is significant for the onset of the illness. It is this event which manifests itself in a perceptible manner in the phase of '*attitudes passionnelles*'; but it is also present when the attack appears to consist only of motor phenomena. The *content of the memory* is as a rule either a psychical *trauma* which is qualified by its intensity to provoke the outbreak of hysteria in the patient or is an event which, owing to its occurrence at a particular moment, has become a trauma.

In cases of what is known as 'traumatic' hysteria this mechanism is obvious to the most cursory observation; but it can be demonstrated also in hysteria where there is no single major trauma. In such cases we find repeated minor traumas or, where the factor of disposition predominates, memories which are often indifferent in themselves magnified into traumas. A trauma would have to be defined as an *accretion of excitation* [*Erregungszuwachs*][T] in the nervous system,[1] *which the latter has been unable to dispose of adequately by motor reaction*. A hysterical *Erregung*

1 [Cf. the paper on organic and hysterical paralyses (1893*c*), p. 199 *n*. 1 below.]

attack is *perhaps* to be regarded as an attempt to complete the reaction to
[138] the trauma. – I may refer here to a work on this subject which has been begun in collaboration with Dr Josef Breuer.[1]

P. 137 [Charcot had described cases in which well-brought-up boys had hysterical attacks accompanied by outbreaks of obscene language.]

Can it be a matter of chance that attacks in young people of whose good upbringing and manners Charcot speaks highly take the form of ravings and abusive language? This is no more the case, I think, than the familiar fact that the hysterical deliria of nuns revel in blasphemies and erotic pictures.[2] In this we may suspect a connection which allows us a deep insight into the mechanism of hysterical states. There emerges in hysterical deliria material in the shape of ideas and impulsions to action which
Hemmung the subject in his healthy state has rejected and inhibited [*gehemmt*][T] – has often inhibited by a great psychical effort. Something similar holds good of a number of dreams, which spin out further associations which have been rejected or broken off during the day.[3] I have based on this fact the theory of 'hysterical counterwill'[4] which embraces a good number of hysterical symptoms.

P. 142 [Charcot was discussing a case exhibiting symptoms both of tic and of obsessions.]

Here I may recall an interesting case which I observed recently which showed a new variant in the relation between tic and obsession [*Zwangsvorstellung*][T]. A man aged 23 consulted me on account of obsessions of a typical kind. From the age of 8 to 15 he had suffered from a lively tic, which has disappeared since then. The obsessions appeared at the age of 12 and have become much more severe recently.

[139] P. 210 [Freud has a long footnote dealing with an elaborate discussion of Charcot's, who maintained that in certain cases complete

1 [Cf. Section IV of the 'Preliminary Communication' (1893*a*), *RSE*, **2**, 12 ff. An early draft of this had been drawn up, probably by Freud himself, towards the end of 1892. It is included here, on p. 179 ff. below.]

2 [Cf. an Editors' footnote on p. 153 above, where a number of other references are given.]

3 [This is a remarkably early reference to the psychodynamics of the dream. Cf. p. 131 and *n.* 1 above.]

4 [See the discussion of this in 'A Case of Successful Treatment by Hypnotism' (1892–93*a*), p. 152 ff. above.]

hemianaesthesia could occur owing to a particular kind of central organic lesion and was in such cases exactly similar to hysterical hemianaesthesia. In particular, Charcot denied that in these cases hemianopsia was present.]

. . . When on one occasion I ventured to question him on this point and to argue that this contradicted the theory of hemianopsia, I was met by this excellent comment: 'La théorie c'est bon; mais ça n'empêche pas d'exister.' If one only knew *what* exists! . . .[1]

P. 224 [Charcot had declared that heredity was the 'true cause' of a patient's hysterical attacks, his vertigo and his agoraphobia.]

I venture upon a contradiction here. The more frequent cause of agoraphobia as well as of most other phobias lies not in heredity but in abnormalities of sexual life. It is even possible to specify the form of abuse of the sexual function involved. Such disorders can be *acquired* in any degree of intensity; naturally they occur more intensely, with the same aetiology, in individuals with a hereditary disposition.

P. 237 [Charcot was discussing a case of Graves' disease.]

Some readers will probably, like me, object to Charcot's aetiological theory which does not separate the disposition to neuroses from that to organic nervous diseases, which takes no account of the part played by *acquired* nervous diseases (which cannot be overestimated) and which makes an arthritic tendency in relatives figure as a hereditary neuropathic disposition. His overestimation of the part played by the factor of heredity may also explain the fact that, in dealing with Graves' disease, Charcot [140]
does not mention the organ in whose changes, as weighty indications tell us, we must look for the true cause of the affection. I refer, of course, to the thyroid gland and, in connection with the discussion of the fact that hereditary disposition and psychical trauma play a large part in the development of the disease, I may mention Moebius's excellent paper on Graves' disease in the *Deutsche Zeitschrift für Nervenheilkunde*, **1** (1891).

1 [This was perhaps Freud's favourite anecdote about Charcot, and he tells it in many places. In his obituary of Charcot (where a list of these can be found) he tells it differently. There the objection was raised anonymously, by 'one of us', and the point at issue was the much simpler question of the dictates of the Young–Helmholtz theory (of colour vision). Since hemianopsia can affect only particular colours, however, the anecdotes may yet be reconcilable. (*RSE*, **3**, 13.)]

P. 268 [Charcot was discussing the distinction between organic and hysterical aphasia.]

When I left the Salpêtrière in 1886, Charcot set me the task of carrying out a comparative study of organic and hysterical paralyses on the basis of the observations made by the Salpêtrière. I have carried out the work but not published it. Its outcome was a further extension of the thesis laid down here by Charcot: hysterical paralyses are characterized by two factors and, in particular, beyond that, by a concurrence between them. They are capable, in the first place, of the *greatest intensity* and, in the second place, of the *sharpest isolation*, and they diverge especially from organic paralyses when they combine intensity and isolation. *A monoplegia of the arm from an organic cause can be limited exclusively to the arm; but in that case it is almost never absolute*. As soon as its intensity increases, it also becomes more extensive; it is positively the rule that it is then accompanied as well by a slight degree of paresis in the face and in the leg. If it is limited to the arm alone and at the same time absolute, the paralysis can only be hysterical.[1]

PP. 283–6 [Charcot had been giving technical advice on the use of suggestion: 'The English, who are certainly practical people, have in their language a warning: "Do not prophesy unless you are sure." I should like to associate myself with this and should advise you to do so too. Indeed,
[141] if, in an undoubted case of psychical paralysis, you say to the patient with complete confidence: "Stand up and walk!", and if he really does, you may, it is true, ascribe the miracle you have performed to yourself and your diagnosis. But I advise you not to venture too far and to consider from the first how, in the possible case of a failure, you can make certain of a retreat "in good order".']

With these wise words Charcot reveals one of the greatest inconveniences with which the practical use of suggestion in the waking state and under light hypnosis has to reckon. In the long run neither the doctor nor the patient can tolerate the contradiction between the decided denial of the ailment in the suggestion and the necessary recognition of it outside the suggestion.[2]

1 [The paper of Freud's referred to here (1893*c*) was actually published late in July, 1893 (see p. 186 below), while the parts of the present volume were still appearing, as is shown by a second reference to it (quoted on p. 169 below) after its publication. It is included in the present volume (p. 185 below), where further particulars are given.]

2 [Freud's comment is evidence of his growing dissatisfaction with suggestion. (Cf. the Editors' remarks on p. 67 above.)]

P. 314 [Charcot had discussed the case history of a male hysterical patient whose disorder was apparently the outcome of mercurial intoxication.]

The readers of these lectures are probably aware that P. Janet, Breuer and I, as well as other authors, have very recently sought to outline a psychological theory of hysterical phenomena, based on Charcot's own writings (on the explanation of hysterotraumatic paralyses). However robust and promising this theory may seem to us, prudence calls for an admission that no step has hitherto been taken towards showing that hysteria through intoxication or the analogy between hysterical and organic hemiplegia or the origin of hysterical contractures can be subsumed under the basic idea of this line of approach. I hope that this task will not prove insoluble or at least that these facts will not turn out to be irreconcilable with the psychological theory.

P. 368 [Charcot was pointing out the differential diagnosis between organic and hysterical monoplegias.]

In a short work ('Quelques considérations pour une étude comparative des paralysies motrices organiques et hystériques', *Archives de Neurologie*, No. 77, 1893) I have tried to enlarge on this remark of Charcot's and have discussed its relation to the theory of the neuroses.[1] [142]

P. 371 [Charcot was describing the differing attacks shown by a hysterical girl.]

We shall certainly not be misunderstanding Charcot if we conclude from his remarks on '*hystéro-épilepsie à crises mixtes*' and '*à crises séparées*' that the term 'hystero-epilepsy' is thoroughly objectionable and that its use should be entirely dropped. Some of the patients indicated in this way are suffering simply from hysteria; others are suffering from hysteria *and* epilepsy, two disorders which have little internal relationship and only meet by chance in a single individual. A statement such as this may not be unnecessary, since many physicians nevertheless seem to be of the opinion that 'hystero-epilepsy' is an aggravation of hysteria or a transition from it to epilepsy. An intention to convey this meaning no doubt originally underlay the creation of the term 'hystero-epilepsy'.

1 [This is the same paper of Freud's (1893*c*) which he spoke of in an earlier footnote (p. 168 *n.* 1 above) as not yet published.]

But Charcot has long since abandoned any such view, and there is no reason why we should lag behind him on this point.[1]

P. 399 [Charcot had expressed his views on overwork as a cause of 'cerebral neurasthenia'.]

All these aetiological discussions on questions of neurasthenia are incomplete so long as no consideration is given to sexual noxae, which, in my experience, constitute the most important and only indispensable aetiological factor.

P. 404 [On a discussion of hereditary determinants of neuroses.]

. . . The theory of the '*famille névropathique*' is certainly in urgent need of revision.

[143] P. 417 [In a similar connection.]

. . . The conception of the '*famille névropathique*' – which, incidentally, embraces almost everything we know in the form of nervous diseases, organic and functional, systematic and accidental – could scarcely stand up to serious criticism.[2]

1 [Cf. footnote 2 to the article in Villaret on hystero-epilepsy, p. 61 above.]

2 [In his obituary of Charcot (1893*f*), *NSW*, **4**; *RSE*, **3**, 21 f., Freud criticizes the theory of the '*famille névropathique*' (the group of the nervous disorders), in which Charcot included 'all those disorders of the nervous system which can take one another's place reciprocally in inheritance' – among them both tabes and hysteria.]

SKETCHES FOR THE 'PRELIMINARY COMMUNICATION' OF 1893

(1940–41 [1892])

EDITORS' NOTE

SKETCHES FOR THE 'PRELIMINARY COMMUNICATION' OF 1893

The three condensed memoranda which follow were included among the post- [146]
humous writings of Freud in Volume XVII of the *Gesammelte Werke*. (More detailed bibliographical data are attached to each separate draft below.) We are informed by the editors of the German edition that all three of these papers had been in Breuer's possession but were returned by him to Freud in 1909, the year after the publication of the second edition of *Studies on Hysteria*. Freud acknowledged their receipt in a letter dated October 8, 1909: 'Very many thanks for letting me have the old drafts and sketches, which seem to me most interesting. As regards the notes on hysterical attacks [Sketch C below], it must be as you say; but I did not keep the manuscript after it was printed.'

Though the second of these sketches is undated, there can be no doubt that all three of them were written in the latter part of 1892, in preparation for the 'Preliminary Communication' – 'On the Psychical Mechanism of Hysterical Phenomena' (1893*a*), *RSE*, **2**, 3. That work, produced in collaboration with Josef Breuer, was published on January 1 and 15, 1893.

Much of these sketches is in a highly condensed form, but it is possible to discover almost every single element of them, more intelligibly stated, in the 'Preliminary Communication'. There is, however, one remarkable exception. The 'principle of constancy' is stated very clearly, and perhaps for the first time, in Section 5 of Sketch C (p. 182 below); but it is entirely omitted, for some unexplained reason, in the 'Preliminary Communication'. A full account of the history of the 'principle of constancy' is given in an Editors' Appendix on 'Freud's Fundamental Hypotheses', *RSE*, **3**, 59.

(A) LETTER TO JOSEF BREUER[1]

29.6.92 [147]

Honoured friend,

The satisfaction with which I innocently handed you over those few pages of mine has given way to the uneasiness which is so apt to go along with the unremitting pains of thinking. I am tormented by the problem of how it will be possible to give a two-dimensional picture of anything that is so much of a solid as our theory of hysteria. The main question, no doubt, is whether we should describe it historically and lead off with all (or two of the best) case histories or whether, on the other hand, we should start by dogmatically stating the theories we have devised as an explanation.[2] I incline to the second suggestion and would arrange the material thus:

(1) Our theories:

(a) The theorem concerning the constancy of the sum of excitation [*Erregungssumme*][T].[3] *Erregung*

(b) The theory of memory.[4]

(c) The theorem which lays it down that the contents of different states of consciousness are not associated with one another.[5]

1 [First published, *GW*, **17** (1941), 5–6. English trans. (by James Strachey), *CP*, **5** (1950), 25–6, and in a revised form, *SE*, **1** (1966), 147–8. The present translation is a further revised reprint of this. – On June 28, 1892, the day before writing this letter to Breuer, Freud had written one to Fliess telling him that 'Breuer has agreed that the theory of abreaction and the other findings on hysteria which we have arrived at jointly shall be brought out jointly too, in a detailed publication'. (Freud, 1950*a*, Letter 9.) He added that 'a portion of it, which I began by wanting to write alone, is finished'. It is presumably to this that Freud is referring at the beginning of the present letter.]

2 [Exactly the same two alternative methods of exposition were considered by Freud in his last, posthumously published, fragment 'Some Elementary Lessons in Psycho-Analysis' (1940*b* [1938]), *RSE*, **23**, 263.]

3 [This is the earliest recorded mention of the 'principle of constancy', which is stated fully on p. 182 below, in Section 5 of Sketch C.]

4 [See Sections 2, 3 and 4 of Sketch C.]

5 [Cf. Sketch B, pp. 177–8 below.]

(2) The origin of chronic hysterical symptoms: dreams, auto-
hypnosis, affects and the results of absolute traumas[t]. The first
[148] three of these factors relate to disposition, the last relates to
aetiology.[1] The chronic symptoms would seem to correspond to
a normal mechanism; they are displacements [*Verschiebungen*][T]
[subsidiary topic],[2] in part along an abnormal path (internal
alteration), of sums of excitation which have not been released.
Reason for the displacement: attempt at reaction. Reason for the
persistence: theorem (*c*) [above], concerning associative
isolation. – Comparison with hypnosis.[3]

Subsidiary topic: On the nature of the displacement: localization of the chronic hysterical symptoms.

(3) *The hysterical attack*: also an attempt at reaction, by means of recollection, etc.[4]

(4) *The origin of hysterical stigmata*: highly obscure, a few hints.[5]

(5) *The pathological formula of hysteria*: Dispositional and accidental hysteria. The series proposed by me.[6] The magnitude of the sum of excitation, the concept of trauma, the second state of consciousness.[7]

1 [This points to the distinction between 'dispositional' and 'traumatic' hysteria, mentioned in (5) below, and discussed at the end of the first paragraph of Sketch B.]

2 [These words are deleted in the manuscript.]

3 [An alternative version of part of this paragraph has been deleted in the manuscript. After 'the chronic symptoms would seem to correspond to a normal mechanism', this deleted version went on: they are 'attempts at reaction, in part along abnormal paths; what is hysterical about them is that they persist. The reason for their persistence lies in theorem (*c*).']

4 [See Sketch C.]

5 [Cf. an Editors' footnote on these in the first section of 'The Aetiology of Hysteria' (1896*c*), *RSE*, **3**, 200 *n.* 2.]

6 [See the end of the first paragraph of Sketch B, p. 177 below.]

7 [See Sections 2 and 4 of Sketch C below.]

(B) 'III'[1]

In what we have written above we have had to point out as a fact of observation that the recollections lying behind hysterical phenomena are absent from the patient's accessible memory, whereas under hypnosis they can be awakened with hallucinatory vividness. We have also pointed out that a number of such recollections relate to events that occurred in peculiar states (such as cataplexy due to fright, half-dreaming conditions, autohypnosis, and so on), the content of which is not connected associatively with normal consciousness. Thus it was already to that extent impossible for us to discuss what it is that determines the occurrence of hysterical phenomena without first considering a particular hypothesis which seeks to characterize the hysterical disposition. In hysteria, according to this hypothesis, the content of consciousness easily becomes temporarily dissociated and certain complexes[2] of ideas which are not associatively connected easily fly apart. The hysterical disposition is therefore to be looked for where states of this kind either appear spontaneously (from internal causes) or are easily produced by external influences; and we may suppose a series of cases in which these two factors play a part of varying importance.[3] [149]

We describe these states as 'hypnoid';[4] and we emphasize the fact that it is an essential characteristic of them that their content is to a greater or less extent cut off from the remaining content of consciousness and is

1 [First published, *GW*, **17** (1941), 17–18. English trans. (by James Strachey), *CP*, **5** (1950), 31–2; revised reprint in *SE*, **1** (1966), 149–50. The present translation is a revised reprint of the latter. – This is evidently a draft of Section III of the Breuer & Freud 'Preliminary Communication' (1893*a*), *RSE*, **2**, 10–12, which no doubt accounts for the heading.]

2 [An early use of the term by Freud. For a discussion of its history, see the Editors' Note to a paper on legal evidence (1906*c*), ibid., **9**, 80. – Cf. also footnote 1, p. 380 below.]

3 [See the 'Preliminary Communication' (1893*a*), *RSE*, **2**, 11 f. This is the first explicit appearance of what Freud was later to call a 'complemental series', though it had already been mentioned in Sketch A (5) above. For a full discussion, see the Editors' Note to the second paper on anxiety neurosis (1895*f*), *RSE*, **3**, 107–8.]

4 [The earliest appearance of Breuer's term.]

thus deprived of the possibility of being disposed of associatively[1] – just as in dreaming and waking, *a model of two states which differ from each other, we are not inclined to make associations from the one to the other*
[150] *but only within each*.[2] In persons with a hysterical disposition any affect can give rise to a splitting of this kind; and an impression received during the affect would thus become a trauma even though it was not in itself appropriate for acting as one. Moreover, the impression might itself produce the affect. In their fully developed shape these hypnoid states, between which there can be associative connections, form the *condition seconde* so familiar in case histories. But rudiments of such a disposition would seem to be discernible everywhere, and may be developed by appropriate traumas even in non-disposed subjects. Sexual life is especially well suited to provide the content [of such traumas] owing to the very great contrast it presents to the rest of the personality and to its ideas being impossible to react to.[3]

It will be understood that our therapy consists in removing the results of the ideas [*Vorstellungen*][T] that have not been abreacted, either by reviving the trauma in a state of somnambulism, and then abreacting and correcting it, or by bringing it into normal consciousness under comparatively light hypnosis.[4]

1 [Cf. the final paragraph of Sketch C, p. 182 below.]

2 [Owing to the omission of a word in the original manuscript its exact phrasing is obscure; but the general sense seems clear. Cf. the last sentence of Section III of the 'Preliminary Communication' (1893*a*), *RSE*, **2**, 12.]

3 ['*Unreagierbarkeit*', literally 'unreactability'. This should possibly be '*Unabreagierbarkeit*' ('unabreactability').]

4 [Cf. the beginning of Section V of the 'Preliminary Communication', ibid., **2**, 15.]

(C) ON THE THEORY OF HYSTERICAL ATTACKS[1]

So far as we know, there is not as yet any theory of hysterical attacks, but only a description of them, coming from Charcot, which relates to the rare, unabbreviated '*grande attaque hystérique* [major hysterical attack]'. According to Charcot, a 'typical' attack of this kind consists of four phases: (1) the epileptoid phase, (2) the phase of large movements, (3) the phase of '*attitudes passionnelles*',[2] and (4) the phase of terminal delirium. All the multifarious forms of hysterical attacks which the physician has opportunities of observing more frequently than the typical *grande attaque* arise, so Charcot tells us, insofar as these individual phases make themselves independent or are prolonged or modified or omitted. [151]

This description throws no light at all on any connection there may be between the different phases, on the significance of attacks in the general picture of hysteria, or on the way in which attacks are modified in individual patients. Perhaps we shall not be wrong in supposing that the majority of physicians are inclined to regard the hysterical attack as 'a periodic discharge of the motor and psychical centres of the cerebral cortex'.

We have reached our opinions on hysterical attacks by treating hysterical subjects by means of hypnotic suggestion and by questioning them under hypnosis and thus investigating their psychical processes during the attack. The following is a statement of our views on the hysterical attack; and we must preface them by pointing out that we regard it as

1 [First published, *Int. Z. Psychoan. Imago*, **25** (1940), 107–10. Reprinted *GW*, **17** (1941), 9–13. English trans. (by James Strachey), *CP*, **5** (1950), 27–30; and in revised reprint, *SE*, **1** (1966), 151–4. The present translation is a further revised reprint of this latter. – Though the original manuscript is in Freud's handwriting (dated 'Vienna, *End of November*, 1892'), it is said by the German editors to have been written jointly with Josef Breuer. It is a draft of Section IV of the 'Preliminary Communication' (1893*a*), *RSE*, **2**, 12–15. The topic of hysterical attacks was also dealt with by Freud at later stages of his career: in a paper explicitly devoted to the subject (1909*a*), ibid., **9**, and in his discussion of Dostoevsky's 'fits' (1928*b*), ibid., **21**. Cf. also one of Freud's footnotes to his translation of Charcot's *Leçons du mardi*, p. 166 f. above.]

2 [In the 'Preliminary Communication' (1893*a*), *RSE*, **2**, 12, this is explained as 'the hallucinatory phase'.]

indispensable for the explanation of hysterical phenomena to assume the presence of a dissociation – a splitting of the content of consciousness.

[152] (1) The constant and essential content of a (recurrent) hysterical attack is the return of a psychical state which the patient has already experienced earlier – in other words, *the return of a memory*.

We are asserting, then, that the essential portion of a hysterical attack is comprised in Charcot's phase of *attitudes passionnelles*. In many cases it is quite obvious that this phase comprises a memory from the patient's life and frequently, indeed, that memory is always the same one. But in other cases this phase seems to be absent and the attack apparently consists only of motor phenomena – of epileptoid spasms or of a cataleptic or sleeplike state of quiescence; yet even in such cases *examination under hypnosis provides definite proof of a psychical mnemic process* such as is usually revealed openly in the *phase passionnelle*.

The motor phenomena of an attack are never unrelated to its psychical content; either they give a general expression of the accompanying emotion or they correspond exactly to the actions involved in the hallucinatory process.

(2) *The memory which forms the content of a hysterical attack is not any chance one; it is the return of the event which caused the outbreak of hysteria – the psychical trauma*.

This relation is once again manifest in the classical cases of traumatic hysteria such as Charcot demonstrated in male patients, where someone who was not previously hysterical succumbed to a neurosis after a single major fright (such as a railway accident, a fall, etc.). In such cases the content of the attack consists in a hallucinatory reproduction of the event which endangered the subject's life, accompanied perhaps by the trains of thought and sense impressions which passed through his mind at the time. But the behaviour of these patients does not differ from that of common female hysterics; it is an exact model of it. If we examine the content of the attacks of one of the latter in the manner that has been indicated, we come upon events which are equally well calculated in their nature to operate as traumas (e.g. frights, mortifications, disappointments). Here, however, the single major trauma is as a rule replaced by a series of minor ones, which are held together by their similarity or by the fact of forming part of one unhappy story. Such patients, accordingly, often have attacks of different kinds, each with a particular mnemic content. This fact makes it necessary to extend the concept of traumatic hysteria considerably.

In a third group of cases we find that the content of the attacks consists in memories which we should not have judged worthy in themselves of constituting traumas. They evidently owe this to the fact that they happened to be associated by a chance coincidence with a moment at which the subject's hysterical disposition was pathologically intensified and they were thus elevated into traumas. [153]

(3) *The memory which forms the content of a hysterical attack is an unconscious one; or, more correctly, it is part of the second state of consciousness which is present, organized to a greater or less degree, in every hysteria*. Accordingly, that memory is either wholly absent from the patient's recollection when he is in his normal state, or it is present only in a summary fashion. If we can succeed in bringing such a memory entirely into normal consciousness, it ceases to be capable of producing attacks. During an actual attack the patient is partly or wholly in the second state of consciousness. In the latter case the whole attack is covered by amnesia during his normal life; in the former case he is aware of the change in his state and of his motor behaviour, but the psychical events during the attack remain hidden from him. They can, however, be awakened at any time by hypnosis.

(4) The question of the origin of the mnemic content of hysterical attacks coincides with the question of what it is that determines whether an experience (an idea, intention, etc.) shall be taken up into the second consciousness rather than into the normal one. We have discovered with certainty two of these determinants in hysterical subjects:

If a hysterical subject seeks intentionally to forget an experience or forcibly repudiates, inhibits and suppresses an intention or an idea, these psychical acts, as a consequence, enter the second state of consciousness; from there they produce their permanent effects and the memory of them returns as a hysterical attack. (Cf. hysteria in nuns, continent women, well-brought-up boys,[1] people with a hankering after art or the stage, etc.)

Impressions received during unusual psychical states (such as affective states, states of ecstasy or autohypnosis) also enter the second state of consciousness.

It may be added that these two determinants are often combined by internal links, and that there are probably other determinants in addition to these.

1 [Cf. the Editors' footnote on p. 153 above, where a full list of references is given.]

(5) *The nervous system endeavours to keep constant something in its functional relations that we may describe as the 'sum of excitation'. It* [154] *puts this precondition of health into effect by disposing associatively of every sensible accretion of excitation*[1] *or by discharging it by an appropriate motor reaction*.[2] If we start out from this theorem, which, incidentally, has far-reaching implications, we find that the psychical experiences forming the content of hysterical attacks have a characteristic in common. They are all of them *impressions which have failed to find adequate discharge* [*Abfuhr*][T], *abführen* either because the patient refuses to deal with them for fear of distressing mental conflicts, or because (as in the case of sexual impressions) he is forbidden to do so by modesty or social conditions, or, lastly, because he received these impressions in a state in which his nervous system was incapable of fulfilling the task of disposing of them.

In this way, too, we arrive at a definition of a psychical trauma which can be employed in the theory of hysteria: *any impression which the nervous system has difficulty in disposing of by means of associative thinking or of motor reaction becomes a psychical trauma*.

Included (No. XXVIII) in Freud's own collection of abstracts of his early works (1897*b*; *RSE*, **3**). Also included in *NSW*, **4**. The original is in French. The present translation is a revised reprint of the *SE* version.

This paper has a long history behind it, which is related in full by Ernest Jones (1953, 255–7). The subject of the present investigation was apparently suggested by Charcot to Freud, in February, 1886, just before his departure from Paris.[1] In his 'Report on my Studies in Paris and Berlin' (1956*a*), written in April, 1886, very soon after his return to Vienna, Freud writes that his discussions with Charcot 'led to my preparing a paper which is to appear in the *Archives de Neurologie* and is entitled "Vergleichung der hysterischen mit der organischen Symptomatologie" ["A Comparison between Hysterical and Organic Symptomatology"]'. (See pp. 11–12 above.) It thus seems that

1 So Freud tells us at the beginning of the present paper and in a footnote to his translation of a volume of Charcot's *Leçons du mardi* (*Poliklinische Vorträge*, **1**, 268 – Freud, 1892–94*a*), a footnote which, incidentally, contains a synopsis of the earlier part of this paper (p. 168 above). But in his *Autobiographical Study* (1925*d*), *RSE*, **20**, 11, he mentions the idea as originating from himself, and this seems to be confirmed by two letters written to his fiancée from Paris at the time of the event and quoted by Jones (1953, 257).

[158] the paper was already written at this early date;[1] but, rather more than two years later, in a letter to Fliess dated May 28, 1888, he writes: 'The first draft of the "hysterical paralyses" is now finished; it is uncertain when the second will be.' (Freud, 1950*a*, Letter 4.) After another three months he writes again, on August 29: 'I am now at last just finishing the hysterical and organic paralyses, with which I am fairly well pleased' (ibid., Letter 5). Further, in his Preface (also dated 'August, 1888') to his translation of Bernheim's book on suggestion (Freud, 1888–89*a*), he refers to the present subject and speaks of a work upon it 'which is shortly to appear' (p. 86 above). There then follow five years of complete silence, broken once more by a letter to Fliess of May 30, 1893 (1950*a*, Letter 12): 'The book I am sending you today is not very interesting.[2] The hysterical paralyses, smaller and more interesting, is appearing at the beginning of June.' On July 10 (ibid., Letter 13): 'The hysterical paralyses should have appeared long ago; they will probably come out in the August number. It is a very short paper . . . You may remember perhaps that I was already engaged on the question when you were my pupil, and that I gave one of my University lectures on it at that time.' This would have been in the autumn of 1887, when Fliess attended some lectures of Freud's in Vienna. Finally, in another letter to Fliess, of July 24, 1893: 'The hysterical paralyses have at last appeared.'

There is nothing to show the nature of the 'accidental and personal reasons' which Freud speaks of here (p. 187 below) to account for the five years' delay in publishing the apparently completed original draft. (Cf. also p. 79 f.) We cannot tell whether it too was written in French; but, in spite of the German title given to it in his 'Paris Report' (p. 12), it seems probable that it was. For, as we have seen, at the time of their original discussion Charcot seems to have promised to publish the outcome of Freud's investigation in the *Archives de Neurologie*, and he did so seven years afterwards – only a fortnight or so before his own unexpected death.

There is, however, a possible explanation of the delay, which is connected with the position occupied by this paper on the watershed between Freud's neurological and psychological writings. The first three sections of the paper are entirely neurological and were no doubt written in 1888, if not in 1886. But the fourth section must date
[159] from 1893, if only because it quotes the Breuer & Freud 'Preliminary Communication', which appeared at the beginning of that year. The whole of this last section, indeed, is based entirely on the new ideas with which Breuer and Freud had begun to operate – repression, abreaction, the principle of constancy, are all implied here if not named explicitly. Freud's direct contact with these ideas had begun in about 1887, and in the following years he was becoming more and more absorbed in them. It seems not impossible that when he had finished the first draft of this paper he had already begun to have some faint notion of an explanation of the facts contained in it which involved these new ideas, and he may for that reason have held back its publication while he went into the question more deeply.

Finally, a quite minor point may be remarked on, which is of interest as a hint of things to come: the paragraph near the end of the paper which is perhaps Freud's first brief public incursion into social anthropology.

1 It may be remarked that a number of the points made in this paper are to be found in the article on 'Hysteria' published in Volume I of Villaret's encyclopaedia in 1888 (p. 48 ff. above) and elsewhere.

2 A large monograph on the cerebral diplegias of children (1893*b*; *NSW*, **2**).

SOME POINTS FOR A COMPARATIVE STUDY OF ORGANIC AND HYSTERICAL MOTOR PARALYSES

At the time at which, in 1885 and 1886, I was a pupil of M. Charcot's, he was kind enough to entrust me with the task of making a comparative study of organic and hysterical motor paralyses based on the observations of the Salpêtrière, in the hope that it might reveal some general characteristics of the neurosis and lead to a view of its nature. For accidental and personal reasons I have long been prevented from carrying out his commission, and even now I am only bringing forward some results of my researches, leaving on one side the details necessary for a complete statement of my opinions. [160]

I

I must begin with some remarks on organic motor paralyses which, incidentally, are generally accepted. Clinical neurology recognizes two kinds of motor paralysis – *periphero-spinal* (or bulbar) paralysis and *cerebral* paralysis. This distinction agrees entirely with the findings of the anatomy of the nervous system, which show that the course of the motor conductive fibres falls into two sections only: of which the first runs from the periphery to the cells of the anterior horns of the spinal cord and the second from there to the cerebral cortex. The modern histology of the nervous system, founded on the work of Golgi, Ramón y Cajal, Kölliker, etc., expresses these facts in the statement that 'the course of the motor conductive fibres is made up of two *neurons* (cellulo-fibrillary neural units), which meet and enter into relation with each other at the level of the cells known as the motor cells of the anterior horns.' The essential difference between these two sorts of paralysis is, in clinical terms, as follows: *periphero-spinal paralysis is a paralysis 'détaillée', cerebral paralysis is a paralysis 'en masse'*.[1]

1 [In Freud's own summary of the present paper in German (in 1897*b*, No. XXVIII; *RSE*, **3**, 247) he does not translate these terms. They might perhaps be rendered 'discrete' and 'distributed'. – Freud himself played a small but significant part in the establishment of the 'neuron' doctrine, in terms of which he here reformulates the distinction between the two sorts of paralysis (see Shepherd, 1991).]

The type of the former is the facial paralysis in Bell's palsy, the paralysis in acute infantile poliomyelitis, etc. In these disorders each muscle – one might say, each muscle fibre – can be paralysed individu-
[161] ally and in isolation. What happens depends only on the site and extent of the nervous lesion; and there is no fixed rule according to which one peripheral element escapes paralysis while another suffers from it permanently.

Cerebral paralysis, on the contrary, is always a disorder that attacks a large portion of the periphery, a limb, a segment of an extremity or a complicated motor apparatus. It never affects an individual muscle – for instance, the biceps of the arm or the tibialis in isolation; and if there are apparent exceptions to this rule (cortical ptosis, for example), we can see clearly that what are in question are muscles which perform by themselves a function of which they are the sole instrument.

In the cerebral paralyses of the extremities, it can be observed that the distal segments always suffer more than the proximal ones; for instance, the hand is more paralysed than the shoulder. So far as I know, there is no such thing as an isolated cerebral paralysis of the shoulder with the hand retaining its motility, whereas the contrary is the rule in paralyses which are not complete.

In a critical study of aphasia, published in 1891, I endeavoured to show that the cause of this important difference between periphero-spinal and cerebral paralyses is to be looked for in the structure of the nervous system. Each element in the periphery corresponds to an element in the grey matter of the cord, which, as M. Charcot has said, is its nervous termination; the periphery is, so to say, projected upon the grey matter of the cord, point by point and element by element. I have proposed to give the periphero-spinal paralysis *détaillée* the name of *projection paralysis*. But the same is not true of the relations between the elements of the cord and those of the cortex. The number of conductive fibres would no longer be sufficient to give a second projection of the periphery upon the cortex. We must suppose that the fibres running from the cord to the cortex no longer each represent a single element of the periphery but rather a group of them, and even, on the other hand, that one element of the periphery may correspond to several spino-cortical conductive fibres. The fact is that there is a change in arrangement at the connecting point between the two sections of the motor system. I argue, therefore, that the reproduction of the periphery in the cortex is no longer a faithful reproduction point by point, that it is no longer a true projection. It is a

relation by means of what may be termed representative fibres, and for cerebral paralysis I propose the name of *representation paralysis*.[1]

When projection paralysis is total and very extensive, it too, of course, [162] is paralysis *en masse* and its main distinctive characteristic is obliterated. On the other hand, cortical paralysis, which is distinguished among cerebral paralyses by its greater tendency to dissociation, nevertheless always presents the character of a representation paralysis.

The other differences between projection and representation paralyses are well known. I may instance among them the normal nutrition and the integrity of the electrical reactions [of the parts affected] which are associated with the latter. Although they are very important clinically, these signs do not possess the theoretical importance which is to be attributed to the first differential characteristic that we mentioned – paralysis *détaillée* and paralysis *en masse*.

Hysteria has fairly often been credited with a faculty for *simulating* the most various organic nervous disorders. The question arises whether, more precisely, it simulates the characteristics of the two sorts of organic paralyses, whether there are hysterical projection paralyses and hysterical representation paralyses like those in organic symptomatology. Here a first fact of importance emerges. Hysteria never simulates peripherospinal or projection paralyses; hysterical paralyses only share the characteristics of organic representation paralyses. This is a most interesting fact, since Bell's palsy, radial paralysis, etc., are among the commonest disorders of the nervous system.

It is desirable to point out here, in order to avoid any confusion, that I am only dealing with *flaccid* hysterical paralyses and not with hysterical contractures. It appears to me impossible to apply the same rules to hysterical paralyses and contractures. It is only of flaccid hysterical paralyses that it can be maintained that they never affect single muscles (except where the muscle concerned is the sole instrument of a function), that they are always paralyses *en masse* and that in this respect they correspond to representation paralyses or organic cerebral paralyses. Furthermore, in the matter of the nutrition of the paralysed parts and their electrical reactions, hysterical paralyses present the same characteristics as organic cerebral paralyses.

If hysterical paralysis is thus associated with cerebral paralysis and in particular with cortical paralysis, which presents a greater aptitude for

1 [Cf. Freud (1891*b*), *NSW*, **4**, Chapter V. The anatomical conception upon which Freud based the distinction between 'projection' and 'representation' paralysis was actually adumbrated earlier, in his unpublished '*Kritische Einleitung in die Nervenpathologie*' (1983*g* [1885]), *NSW*, **1**, and also in the unsigned article on cerebral anatomy in Villaret's encyclopaedia (1888*b*), *NSW*, **1**.]

dissociation, it is no less distinguished from them by important characteristics. In the first place, it is not bound by the rule, which applies regularly to organic cerebral paralyses, that the distal segment is always more affected than the proximal one. In hysteria, the shoulder or the
[163] thigh may be more paralysed than the hand or the foot. Movements may appear in the fingers while the proximal segment is still absolutely inert. There is not the slightest difficulty in artificially producing an isolated paralysis of the thigh, the leg, etc., and clinically one can quite often come across these isolated paralyses, in contradiction to the rules of organic cerebral paralysis.

In this important respect hysterical paralysis is, so to say, intermediate between organic projection paralysis and representation paralysis. If it does not possess all the characteristics of dissociation and isolation proper to the former, it is far from being submitted to the strict laws that govern the latter – cerebral paralysis. Subject to these qualifications, it may be maintained that hysterical paralysis is also a representation paralysis, but with a special kind of representation whose characteristics remain to be discovered.[1]

II

As a step in that direction, I propose to study the other distinguishing characteristics between hysterical paralysis and cortical paralysis, the most perfect type of organic cerebral paralysis. We have already mentioned the first of these characteristics – the fact that hysterical paralysis can be more dissociated, more systematized, than cerebral paralysis. The symptoms of organic paralysis appear piecemeal, as it were, in hysteria. Among the symptoms of common organic hemiplegia (paralysis of the upper and lower limbs and of the lower part of the face) hysteria reproduces only the paralysis of the limbs and even dissociates, quite often and with the greatest ease, paralyses of the arm and of the leg in the form of monoplegias. From the syndrome of organic aphasia it reproduces motor
[164] aphasia in isolation; and – something unheard of in organic aphasia – it

1 Incidentally I may point out that the property of the neurosis which I have mentioned explains quite simply the important characteristic of hysterical paralysis of the leg to which M. Charcot, following Todd, has drawn attention – namely the fact that the hysteric drags the leg like an inert mass instead of performing a circumduction with the hip as does the ordinary hemiplegic. In organic hemiplegia the proximal portion of the limb is always to some extent exempt; the patient can move his hip and he uses it for the movement of circumduction which brings the leg forward. But in hysteria the proximal portion (the hip) does not enjoy that privilege, the paralysis is as complete in it as in the distal portion, and the leg must consequently be dragged inertly as a whole. [Cf. Charcot (German trans.), 1894, 251–2, quoting Todd, 1856, 21. Freud had indicated this characteristic in his very early paper on a hysterical man (1886*d*), p. 30 above.]

can create total aphasia (motor and sensory) for a particular language without in the slightest interfering with the faculty of understanding and articulating another. (I have observed this in some unpublished cases.)[1] This same power of dissociation is manifested in isolated paralyses of one segment of a limb while other parts of the same limb remain completely unimpaired, or, again, in the total abolition of a function (e.g. in abasia and astasia) while another function performed by the same organs remains intact.[2] This dissociation is all the more striking when the function that is unimpaired is the more complex one. In organic symptomatology, if there is an unequal weakening of several functions, it is always the more complex function, the one that has been more recently acquired, that is most affected as the result of the paralysis.[3]

Furthermore, hysterical paralysis exhibits another characteristic which is, as it were, the hallmark of the neurosis and which comes as an addition to the first one. Hysteria, as I have heard M. Charcot say, is indeed a disease of excessive manifestations; it tends to produce its symptoms with the greatest possible intensity. This characteristic is shown not only in its paralyses but also in its contractures and anaesthesia. We know to what a degree of distortion hysterical contractures can be carried – a degree almost unequalled in organic symptomatology. We know, too, the frequency in hysteria of absolute, profound anaesthesia, of which organic lesions can reproduce only a feeble sketch. It is the same with paralyses. They are often absolute to the most extreme extent. The aphasic utters not a word, whereas the organic aphasic almost always retains a few words, 'yes' or 'no', a swear word, etc.; the paralysed arm is completely inert – and so on. This characteristic is too well known to need insisting upon. In contrast to this, we know that in organic paralysis paresis is always commoner than absolute paralysis.

Hysterical paralysis is thus characterized by *precise limitation* and *excessive intensity*; it possesses both these qualities at once, and it is in this that it shows the greatest contrast to organic cerebral paralysis, in which it is regularly found that *these two characteristics are not associated with each other*. There are monoplegias in organic symptomatology, but they

1 [One of these was no doubt Breuer's case of Anna O., which was later to be included in *Studies on Hysteria* (1895*d*), *RSE*, **2**, 22 f. Cf. the unsigned encyclopaedia article on 'Aphasia' (Freud, 1888*b*), *NSW*, **4**.]

2 [This point, like many others in this paper, appears already in the encyclopaedia article on 'Hysteria' (1888*b*), confirming its attribution to Freud (p. 49 above).]

3 [Freud relied heavily on this dynamic (Jacksonian) principle in his conceptualization of the infantile cerebral palsies (1897*a*), *NSW*, **3**.]

[165] are almost always monoplegias *a potiori*[1] and not precisely delimited. If the arm is paralysed as the result of an organic cortical lesion, there is almost always a minor concomitant affection of the face and leg; and if this complication is not apparent at a particular moment it will certainly have existed at the start of the illness. The truth is that a cortical monoplegia is always a hemiplegia of which one part or another is more or less obliterated but is still recognizable. To go a little further, let us suppose that the paralysis has affected no part other than the arm, that it is a pure cortical monoplegia; the paralysis will then be seen to be of moderate intensity. As soon as this monoplegia increases in intensity and becomes an absolute paralysis, it will lose its character of a pure monoplegia and will be accompanied by motor disorders in the leg or face. *It cannot at the same time become absolute and retain its delimitation.*

This, on the contrary, is what can be achieved quite easily by a hysterical paralysis, as clinical experience shows us daily. For instance, it will affect an arm exclusively and without our finding a trace of it in the leg or face. Moreover, at the arm level it is as severe as a paralysis can be, and there we have a striking difference from an organic paralysis – a difference which gives us decided cause for reflection.

There are, of course, cases of hysterical paralysis in which the intensity is not excessive and in which the dissociation is not in any way remarkable. These can be recognized by other characteristics; but they are cases which do not carry the typical mark of the neurosis, and which, since they can teach us nothing of its nature, are not of any interest from our present point of view.

I will add a few comments which are of secondary importance and are even somewhat outside the limits of our topic.

In the first place I may point out that hysterical paralyses are much more frequently accompanied by disorders of sensibility than are organic paralyses. Such disturbances are in general more profound and more frequent in neuroses than in organic symptomatology. Nothing is commoner than hysterical anaesthesia or analgesia. It will, on the other hand, be recalled with what tenacity sensibility persists where there is a neural lesion. If a peripheral nerve is severed, the anaesthesia will be less in extent and intensity than would have been expected. If an inflammatory lesion attacks the spinal nerves or the centres in the spinal cord, we always find that motility is the first thing to suffer and that sensibility is spared or merely weakened, for somewhere or other neural elements [166] always persist which have not been totally destroyed. Where there is a

1 [I.e. described as such from their dominant feature.]

cerebral lesion, we are familiar with the frequency and duration of the motor hemiplegia, while the accompanying hemianaesthesia is indistinct and transitory and is not present in every case. It is only a few quite special localizations of the lesion which can produce an intense and lasting disturbance of sensibility (confluence of sensory pathways), and even this fact is open to doubt.

This behaviour of sensibility, differing in organic lesions and in hysteria, is scarcely explicable at present. We seem to have here a problem whose solution might perhaps throw light on the intimate nature of the phenomena.

Another point which seems to me to deserve mention is that there are certain forms of cerebral paralysis which are not found in hysteria any more than are the periphero-spinal projection paralyses. Such, in the first place, is paralysis of the lower half of the face, the most frequent manifestation of an organic disease of the brain, and (if I may be allowed to pass for a moment to sensory paralyses) homonymous lateral hemianopsia. I am conscious that it is almost risking a wager to assert that such and such a symptom is not found in hysteria, when the researches of M. Charcot and his pupils find in it – one might say every day – fresh symptoms which had not been suspected previously. But I must take things as they are at the moment. The occurrence of hysterical facial paralysis is strongly disputed by M. Charcot, and, even if we believe its partisans, is a phenomenon of great rarity. Hemianopsia has not yet been observed in hysteria, and, I believe, never will be.

How is it, then, that hysterical paralyses, while closely simulating cortical paralyses, diverge from them by the distinctive characteristics which I have tried to enumerate? And what is the general character of the special sort of representation with which they must be associated? The answer to this question would include a large and important part of the theory of the neurosis.

III

There is not the slightest doubt as to the conditions which dominate the symptomatology of cerebral paralysis. They are the facts of anatomy – the construction of the nervous system and the distribution of its vessels – and the relation between these two series of facts and the circumstances of the lesion. We have pointed out that the lesser number of the fibres running from the spinal cord to the cortex in comparison with the number of fibres running from the periphery to the cord is the basis

[167] of the difference between projection and representation paralysis. In the same way every clinical detail of representation paralysis can be explained by some detail of cerebral structure; and, conversely, we can deduce the construction of the brain from the clinical characteristics of the paralyses. I believe there is a complete parallelism between these two series.

Thus, if there is no great facility for dissociation in ordinary cerebral paralysis, that is because the motor fibres run too close together over a long stretch of their intracerebral course for them to be damaged individually. If cortical paralysis shows more tendency to being monoplegic, that is because the diameter of the conducting bundles (brachial, crural, etc.) increases towards the cortex. If paralysis of the hand is the most complete of all the cortical paralyses, that, we believe, is due to the fact that the crossed relation between the cerebral hemisphere and the periphery is more exclusive in the case of the hand than of any other part of the body. If the distal segment of an extremity suffers more from paralysis than the proximal one, we suppose that the representative fibres of the distal segment are far more numerous than those of the proximal one, so that cortical influence becomes more important for the former than it is for the latter. If fairly extensive lesions of the cortex do not succeed in producing pure monoplegias, we infer that the motor centres in the cortex are not sharply separated from one another by neutral territory, or that there are factors operating at a distance (*Fernwirkungen*[1]), which would seem to cancel the effect of a precise separation of the centres.

In the same way, if in organic aphasia there is always a mixture of disturbances of various functions, that is to be explained by the fact that branches of the same artery nourish all the speech centres, or, if the opinion expressed in my critical study of aphasia [Freud, 1891*b*; *NSW*, **4**] is accepted, by the fact that we are dealing not with separate centres but with a continuous area of association. However that may be, an explanation derived from anatomy is always to be found.

The remarkable associations that are so often observed clinically in cortical paralyses (motor aphasia and right hemiplegia, alexia and right hemianopsia) are explained by the propinquity of the damaged centres. Hemianopsia itself, a symptom that is very curious and strange to a non-scientific mind, is only explicable by the crossing of the fibres of the optic nerve at the chiasma; it is a clinical expression of it, just as every detail of the cerebral paralyses is the clinical expression of a fact of anatomy.

1 [In German in the original.]

Since there can only be a single cerebral anatomy that is true, and since it finds expression in the clinical characteristics of the cerebral paralyses, it is clearly impossible for that anatomy to be the explanation of the distinctive features of hysterical paralyses. For that reason we must not draw conclusions on the subject of cerebral anatomy that are based on the symptomatology of those paralyses. [168]

In order to explain this difficult problem we must certainly consider the nature of the lesion concerned. In organic paralyses the *nature* of the lesion plays a secondary part; it is rather the extent and localization of the lesion which, in the given structural conditions of the nervous system, produce the characteristics of organic paralysis which we have indicated. What might be the nature of the lesion in hysterical paralysis, which dominates the situation, without regard to the localization or extent of the lesion or of the anatomy of the nervous system?

We have several times heard from M. Charcot that it is a cortical lesion, but one that is purely dynamic or functional. This is a thesis whose negative aspect we can well understand: it is equivalent to asserting that no appreciable tissue changes will be found *post mortem*. But in its positive aspect its interpretation is far from being unequivocal. What, after all, is a dynamic lesion? I am quite sure that many who read M. Charcot's works believe that a dynamic lesion is indeed a lesion, but one of which no trace is found after death, such as an oedema, an anaemia or an active hyperaemia. These, however, although they may not necessarily persist after death, are true organic lesions even if they are slight and transitory. Paralyses produced by lesions of this order would necessarily share the characteristics of organic paralyses. Neither oedema nor anaemia, any more than haemorrhage or softening [infarction], could produce the dissociation and intensity of hysterical paralyses. The only difference would be that paralysis due to oedema, by vascular constriction, etc., would be less lasting than paralysis due to destruction of nervous tissue. They have all the other conditions in common, and the anatomy of the nervous system will determine the properties of the paralysis as much in the case of a transitory anaemia as in that of one that is permanent and final.

These remarks do not seem to me entirely gratuitous. If one reads that 'there must be a hysterical lesion' in such and such a centre, the same centre in which an organic lesion would produce a corresponding organic syndrome, and if one recalls that one is accustomed to localize a hysterical dynamic lesion in the same manner as an organic lesion, one is led to believe that behind the expression 'dynamic lesion' there is hidden

[169] the idea of a lesion like oedema or anaemia, which are in fact transitory organic affections. I, on the contrary, assert that the lesion in hysterical paralyses must be completely independent of the anatomy of the nervous system, since *in its paralyses and other manifestations hysteria behaves as though anatomy did not exist or as though it had no knowledge of it*.[1]

And in fact a good number of the characteristics of hysterical paralyses justify this assertion. Hysteria is ignorant of the distribution of the nerves, and that is why it does not simulate periphero-spinal or projection paralyses. It has no knowledge of the optic chiasma, and consequently it does not produce hemianopsia. It takes the organs in the ordinary, popular sense of the names they bear: the leg is the leg as far up as its insertion into the hip, the arm is the upper limb as it is visible under the clothing. There is no reason for adding paralysis of the face to paralysis of the arm. A hysteric who cannot talk has no motive for forgetting his comprehension of speech, since motor aphasia and word deafness are unrelated to each other in the popular mind, and so on. I can only associate myself fully with the views advanced by M. Janet in recent numbers of the *Archives de Neurologie*; they are confirmed as much by hysterical paralyses as by anaesthesia and psychical symptoms.

IV

I will attempt to indicate, finally, what the lesion that is the cause of hysterical paralyses might be like. I do not say that I will show what it *is* like; it is merely a question of indicating a line of thought that might lead to a conception which does not contradict the properties of hysterical paralysis insofar as it differs from organic cerebral paralysis.

I shall take the phrase 'functional or dynamic lesion' in its proper sense of 'alteration in function or dynamics' – alteration of a functional property. Examples of an alteration of this kind would be a diminution in excitability [*l'excitabilité*] or in a physiological quality which normally remains constant or varies within fixed limits.

But, it will be objected, functional alteration is not a different thing from organic alteration, it is merely another side of it. Let us suppose that nervous tissue is in a state of transitory anaemia; then its excitability will be diminished by this circumstance. It is impossible by this expedient to avoid taking organic lesions into account.

1 [A phrase very similar indeed to this can be found in the encyclopaedia article on 'Hysteria' (1888*b*), p. 51 above.]

I will try to show that there *can* be a functional alteration without a concomitant organic lesion – or at least without one that is grossly palpable even by the most delicate analysis. In other terms, I will give a suitable example of an alteration of a primitive function; and for that purpose I only ask permission to move on to psychological ground – which can scarcely be avoided in dealing with hysteria. [170]

I follow M. Janet in saying that what is in question in hysterical paralysis, just as in anaesthesia, etc., is the everyday, popular conception[1] of the organs and of the body in general. That conception is not founded on a deep knowledge of neuroanatomy but on our tactile and above all our visual perceptions. If it is what determines the characteristics of hysterical paralysis, the latter must naturally show itself ignorant and independent of any notion of the anatomy of the nervous system. The lesion in hysterical paralysis will therefore be an alteration of the *conception*, the *idea*, of the arm, for instance. But what kind of alteration must this be in order to produce paralysis?

Considered psychologically, the paralysis of the arm consists in the fact that the conception of the arm cannot enter into association with the other ideas constituting the ego [*moi*] of which the subject's body forms an important part. The lesion would therefore be *the abolition of the associative accessibility of the conception of the arm*. The arm behaves as though it did not exist for the play of associations. There is no doubt that, if the material conditions corresponding to the conception of the arm are profoundly altered, the conception will also be lost. But I have to show that it can be inaccessible without being destroyed and without its material substratum (the nervous tissue of the corresponding region of the cortex) being damaged.

I will begin with some examples drawn from social life. A comic story is told of a loyal subject who would not wash his hand because his sovereign had touched it. The relation of this hand to the idea of the king seemed so important to the man's psychical life that he refused to let the hand enter into any other relation. We are obeying the same impulse when we break the glass in which we have drunk the health of a young married couple. Savage tribes in antiquity, who burnt their dead chief's horse, his weapons and even his wives along with his dead body, were obeying this idea that no-one should ever touch them after him. The force of all these actions is clear. The quota of affect[2] which we attribute

1 ['*Conception*' in French. Presumably the German word Freud had in mind was '*Vorstellung*', which is usually translated 'idea' in this edition. Several lines down he uses '*la conception*' and '*l'idée*' synonymously. See *RSE*, **24**, 94–8.]

2 ['*Valeur affective*.' See footnote 5, p. 198 below.]

[171] to the first association of an object has a repugnance to letting it enter into a new association with another object and consequently makes the idea of the [first] object inaccessible to association.[1]

It is not a mere comparison, it is almost the identical thing, when we move into the sphere of the psychology of conceptions. If the conception of the arm is involved in an association with a large quota of affect, it will be inaccessible to the free play of other associations. *The arm will be paralysed in proportion to the persistence of this quota of affect or to its diminution by appropriate psychical means*. This is the solution to the problem we have raised, for, in every case of hysterical paralysis, we find that *the paralysed organ or the lost function is involved in a subconscious*[2] *association which is provided with a large quota of affect and it can be shown that the arm is liberated as soon as this quota is wiped out*. Accordingly, the conception of the arm exists in the material substratum, but it is not accessible to conscious associations and impulses because the whole of its associative affinity, so to say, is saturated in a subconscious association with the memory of the event, the trauma, which produced the paralysis.[3]

M. Charcot was the first to teach us that to explain the hysterical neurosis we must apply to psychology. Breuer and I have followed his example in a preliminary communication (1893*a*) 'On the Psychical Mechanism of Hysterical Phenomena'. We show in that paper that the permanent symptoms of hysteria which are described as 'non-traumatic' are explained (apart from the stigmata[4]) by the same mechanism which Charcot recognized in traumatic paralyses. But we also give the reason for the persistence of these symptoms and show why they can be cured by a special procedure of hypnotic psychotherapy. Every event, every psychical impression is provided with a certain quota of affect
[172] (*Affektbetrag*)[5] of which the ego divests itself either by means of a motor reaction or by associative psychical activity. If the subject is unable or unwilling to get rid of this surplus, the memory of the impression attains the importance of a trauma and becomes the cause of

1 [Freud made use of this fact in explaining a point in the theory of dream formation. See Chapter VII (C) of *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 503 f.]

2 [*subconsciente*. One of the very few occurrences of the word (and perhaps the earliest) in Freud's writings. See a note on its use in *Studies on Hysteria* (1895*d*), ibid., **2**, 41 *n.* 2.]

3 [In his case history of Frau Emmy von N., Freud quotes her symptom of anorexia in support of the present theory. See ibid., **2**, 78–80.]

4 [Cf. an Editors' footnote on these in 'The Aetiology of Hysteria' (1896*c*), ibid., **3**, 200 *n.* 2.]

5 [In German in the original. Cf. a discussion of this in an Editors' Appendix to Freud's first paper on the neuropsychoses of defence (1894*a*), ibid., **3**, 60 f. Breuer uses the term '*Affektwert*', a more literal equivalent of the French '*valeur affective*'. Cf. *Studies on Hysteria*, ibid., **2**, 190 *n*.]

permanent hysterical symptoms. The impossibility of elimination becomes evident when the impression remains in the subconscious. We have called this theory '*Das Abreagieren der Reizzuwächse*'.[1]

To sum up, I think that it is in complete agreement with our general view of hysteria, as we have been able to shape it under M. Charcot's instruction, to suppose that the lesion in hysterical paralyses consists in nothing other than the inaccessibility of the organ or function concerned to the associations of the conscious ego; that this purely functional alteration (even the conception remaining unimpaired) is caused by the fixation[2] of this conception in a subconscious association with the memory of the trauma; and that this conception does not become liberated and accessible so long as the quota of affect of the psychical trauma has not been eliminated by an adequate motor reaction or by conscious psychical activity. But even if this mechanism does not occur, if a direct autosuggestive idea is always necessary for hysterical paralysis, as it is in M. Charcot's traumatic cases, we have succeeded in showing what the nature of the lesion, or rather of the alteration, in hysterical paralysis *would have* to be in order to explain the differences between it and organic cerebral paralysis.

1 [In German in the original. 'The Abreaction of Accretions of Stimulus.' The phrase seems scarcely to appear elsewhere, apart from an occurrence in the report of the lecture on 'The Psychical Mechanism of Hysterical Phenomena' (1893*h*), *RSE*, **3**, 35 f. The term *Reizzuwächse* occurs in 'Formulations on the Two Principles of Mental Functioning' (1911*b*), ibid., **12**, 217. The term '*Erregungszuwachs*' ('accretion of excitation') occurs in a footnote by Freud added to his translation of Charcot's *Leçons du mardi* (*Poliklinische Vorträge*, **1**, 107 – Freud, 1892–94*a*, p. 165 above), in Sketch C for the 'Preliminary Communication' (p. 179 above) and in Draft E in the Fliess papers (p. 220 below). Breuer also uses it twice in his theoretical contribution to *Studies on Hysteria* (1895*d*), *RSE*, **2**, 178–9.]

2 [See footnote, p. 152 above.]

EXTRACTS FROM THE FLIESS PAPERS

(1950 [1892–99])

Sigmund Freud with Wilhelm Fliess in the early 1890s

Sigmund Freud with Wilhelm Fliess in the early 1890s

In a letter to Fliess dated April 2, 1896, Freud wrote: 'If we are both granted a few more years of quiet work, we shall certainly leave behind something which will justify our existence. That feeling strengthens me against all daily cares and worries. When I was young, the only thing I longed for was philosophical knowledge, and now that I am going over from medicine to psychology I am in the process of attaining it.'

1950 In *Aus den Anfängen der Psychoanalyse*, edited by Marie Bonaparte, Anna Freud & Ernst Kris, London: Imago Publishing Co. (Abridged.) [175]

1986 S. Freud, *Briefe an Wilhelm Fliess 1887–1904* (edited by J. M. Masson), Frankfurt am Main: S. Fischer Verlag. (Unabridged.)

ENGLISH TRANSLATIONS

1954 In *The Origins of Psycho-Analysis*, edited as above, London: Imago Publishing Co.; New York: Basic Books. (Abridged.) (Tr. Eric Mosbacher & James Strachey.)

1966 *SE*, **1**, 177–387. (Selected letters only.) (Revised version of the 1954 translations.)

1985 *The Complete Letters of Sigmund Freud to Wilhelm Fliess 1887–1904*, Cambridge, MA, and London: Harvard University Press. (Unabridged.) (Tr. Jeffrey Masson.)

The present translation is a revised and corrected version of the *SE* one.

The history of Freud's relations with Wilhelm Fliess (1858–1928) is fully narrated in Chapter XIII of the first volume of Ernest Jones's biography of Freud (1953) and in Ernst Kris's introduction to the earliest books in the bibliography above. Here it is only necessary to explain that Fliess, a man two years younger than Freud, was a nose and throat specialist living in Berlin with whom Freud carried on a voluminous and intimate correspondence between 1887 and 1902. Fliess was a man of great ability, with very wide interests in general biology; but he pursued theories in that field which are regarded today as eccentric and quite untenable. He was, however, more amenable to Freud's ideas than any other contemporary. Freud accordingly communicated his thoughts to him with the utmost freedom and did so not only in his letters but in a series of papers ('Drafts' as they are called here) which presented organized accounts of his developing views and are in some cases first sketches of his later published works. The most important of these papers is the long one – some forty thousand words – to which we have given the title of 'Project for a Scientific Psychology'. But the whole series, written as it was during the formative years of Freud's psychoanalytic theories culminating in *The Interpretation of Dreams*, deserves the closest study.

These papers, and even the fact of their existence, were totally unknown until the
[176] time of the Second World War.[1] The melodramatic story of their discovery and rescue is also told by Ernest Jones in the same chapter of his biography. Our principal debt over the whole business is to Princess Marie Bonaparte (Princess George of Greece), who not only acquired the papers in the first instance but had the remarkable courage to defy the efforts to destroy them made by their author and her teacher.

Only a selection from these papers was published in 1950. And for the *Standard Edition* James Strachey made a further selection from that selection. Although the unabridged correspondence has since become available, we have not found it necessary to extend Strachey's selection for the *Revised Standard Edition*. We have chosen (*a*) the 'Project for a Scientific Psychology', (*b*) all but one of the 'Drafts', and (*c*) such portions of the letters as seem to have a significant bearing on the history of psychoanalysis and the development of Freud's views. The reader will do well to bear in mind that the material in these drafts and letters was not intended by their author as the considered expression of his opinions, and that it is often framed in a highly condensed form. Surprise need not therefore be felt at the occasional presence of inconsistencies and obscurities.

The present translation is based on the revised German version printed in 1986. Significant deviations from the 1950 version are mentioned in the Editors' footnotes. The lettering and numbering of the drafts and letters in the 1950 (and 1954 English) editions have been retained for simplicity of reference, and for the reasons explained in the Editor's preface above (p. xxx). We have followed the editors of the *Anfänge* (for reasons explained below, p. 247) in detaching the 'Project' from the rest of the correspondence and printing it at the end of the volume.

1 Fliess's side of the correspondence has not survived, having no doubt been destroyed long since.

EXTRACTS FROM THE FLIESS PAPERS

DRAFT A[1]

PROBLEMS

(1) Is the anxiety [*Angst*][T] of anxiety neuroses derived from the inhibition [*Hemmung*][T] of the sexual function [*Sexualfunktion*][T] or from the anxiety linked with their aetiology? [177] *Sexual*
(2) To what extent does a healthy person respond to later sexual traumas differently from someone with a disposition due to masturbation? Only quantitatively? Or qualitatively?
(3) Is simple *coitus reservatus* (condom) a noxa at all?[2]
(4) Is there an innate neurasthenia with innate sexual weakness or is it always acquired in youth? (From nurses, from being masturbated by someone else.)[3]
(5) Is heredity anything other than a multiplier?[4]
(6) What plays a part in the aetiology of periodic depression?

1 [Undated. The editors of the *Anfänge*, 74 *n*., suggest that it was written towards the end of 1892. Freud and Fliess were at that time working on the problem of neurasthenia. Ingeborg Meyer-Palmedo suggests that the dating is confirmed by the fact that Freud promises in a letter dated January 5, 1893, to *re*write the 'Aetiology of the Neuroses', which he then submitted to Fliess on February 8, 1893 (Draft B). At all events, Draft A deals with much the same topics as Draft B, in abbreviated form. All these early drafts, up to and including Draft E, are mainly concerned with anxiety neurosis and neurasthenia, questions which were brought to a head in the first paper on anxiety neurosis (1895*b*), published on January 15, 1895. – This manuscript is almost unique in being written, for some unknown reason, in Roman script instead of Freud's usual Gothic. In a letter to Ernest Jones of November 20, 1926, Freud wrote: 'You will be astonished when I disclose what it is that hinders my correspondence with you. It is a classic example of the petty restrictions to which our nature is subject. It is that I find it very hard to write German in Roman characters, as I am now doing. All fluency – inspiration one would say on a higher plane – at once leaves me. You have often told me that you cannot read Gothic handwriting.' (Jones, 1957, 138.)]

2 [Freud seems to be asking whether *coitus reservatus* is a noxa when there is no previous history of masturbation. He replies to this question in the affirmative in Draft B, p. 209 below.]

3 [This seems to be the first indication of the general hypothesis of sexual seduction in the aetiology of neuroses, assuming the dating of this draft is correct.]

4 [This analogy from an electric circuit appears (among other places) in the second paper on anxiety neurosis (1895*f*), *RSE*, **3**, 123 and *n*.]

(7) Is sexual anaesthesia in women anything other than a result of impotence? Can it of itself cause neuroses?[1]

THESES

[178] (1) No neurasthenia or analogous neurosis exists without a disturbance of the sexual function.
(2) This either has an immediate causal effect or acts as a disposition for other factors, but always in such a way that without it the other factors cannot bring about neurasthenia.
(3) Neurasthenia in men, on account of its aetiology, is accompanied by relative impotence.
(4) Neurasthenia in women is a direct consequence of neurasthenia in men, through the agency of this reduction in their potency.
(5) Periodic depression is a form of anxiety neurosis, which, apart from this, is manifested in phobias and anxiety attacks.
(6) Anxiety neurosis is in part a consequence of inhibition of the sexual function.
(7) Simple excess and overwork are not aetiological factors.[2]
(8) Hysteria in neurasthenic neuroses indicates suppression of the accompanying affects.

GROUPS [FOR OBSERVATION]

(1) Men and women who have remained healthy.
(2) Sterile women, where preventive traumas in marriage are absent.
(3) Women infected with gonorrhoea.
(4) Loose-living men who are gonorrhoeal, and who are on that account protected in every respect, being aware of their hypospermia.
(5) Members of severely tainted families who have remained healthy.
(6) Observations from countries in which particular sexual abnormalities are endemic.

AETIOLOGICAL FACTORS

(1) Exhaustion owing to abnormal [forms of] satisfaction. Example: masturbation.

1 [Note at the bottom of MS. page:] Delusion of smallness, sexual inadequacy.

2 [This view is expressed repeatedly in Freud's early writings, e.g. Freud (1895*b*), *RSE*, **3**, 94, and (1898*a*), ibid., **3**, 267, but was qualified later in (1937*c*), ibid., **23**, 204 *n*. 2.]

(2) Inhibition of the sexual function. Example: *coitus interruptus*.
(3) Affects accompanying these practices.
(4) Sexual traumas before the age of understanding.

DRAFT B
THE AETIOLOGY OF THE NEUROSES[1]

I am writing the whole thing down a second time, for you, my dear friend, and for the sake of our common labours. You will of course keep the draft away from your young wife. [179]

1. It may be taken as a recognized fact that *neurasthenia* is a frequent consequence of an abnormal sexual life. The assertion, however, which I wish to make and to test by my observations is that neurasthenia is always *only* a sexual neurosis.

I have adopted a similar point of view (along with Breuer) in regard to hysteria. Traumatic hysteria was well known; what we asserted beyond this was that *every* hysteria that is not hereditary is traumatic.[2] In the same way I am now asserting that *every* neurasthenia is sexual.

We will for the moment leave on one side the question of whether hereditary disposition and, secondarily, toxic influences can produce genuine neurasthenia, or whether what appears to be hereditary neurasthenia in fact also goes back to early sexual exhaustion. If there is such a thing as hereditary neurasthenia, the questions arise of whether the *status nervosus* in the hereditary cases should not be distinguished from neurasthenia, what relation at all it has to the corresponding symptoms in childhood, and so on.

In the first instance, therefore, my contention will be restricted to *acquired* neurasthenia. What I am asserting can accordingly be formulated as follows. In the aetiology of a nervous affection we must distinguish (1) the necessary precondition without which the state cannot come about at all, and (2) the precipitating factors. The relation between these two can be pictured thus. If the necessary precondition has operated sufficiently, the affection sets in as an inevitable consequence; if it

1 [Dated, from the postmark, February 8, 1893. This, as is shown by the introductory sentence, is a fresh version of an earlier paper which is presumably Draft A (see p. 205 above). In a letter to Fliess of January 5, 1893, Freud remarks: 'I am rewriting the thing on the neuroses.' Here, as quite often at this period, by 'neuroses' Freud meant neurasthenia and anxiety neurosis – the later 'actual neuroses'. (See *RSE*, **2**, 78, and **3**, 37 and 273 *n*. 1.) The substance of the present draft emerged nearly two years later in the first paper on anxiety neurosis (1895*b*).]

2 [The Breuer & Freud 'Preliminary Communication' (1893*a*) had been published a month before this.]

[180] has not operated sufficiently, the result of its operation is in the first place a disposition to the affection which ceases to be latent as soon as a sufficient amount of one of the secondary factors supervenes. Thus what is lacking for full effect in the first aetiology can be replaced by the aetiology of the second order. The aetiology of the second order can, however, be dispensed with, while that of the first order is indispensable.[1]

If this aetiological formula is applied to our present case, we arrive at this. Sexual exhaustion can by itself alone provoke neurasthenia. If it fails to achieve this by itself, it has such an effect on the disposition of the nervous system that physical illness, depressive affects and overwork (toxic influences) can no longer be tolerated without [leading to] neurasthenia. Without sexual exhaustion, however, all these factors are incapable of generating neurasthenia. They bring about normal fatigue, normal sorrow, normal physical weakness, but they only continue to give evidence of how much 'of these detrimental influences a normal person can tolerate'.[2]

I will consider neurasthenia in men and in women separately.

Neurasthenia in males is acquired at puberty and becomes manifest in the patient's twenties. Its source is masturbation, the frequency of which runs completely parallel with the frequency of male neurasthenia.[3] One can observe in the circle of one's acquaintances that (at all events in urban populations) those who have been seduced by women at an early age have escaped neurasthenia. When this noxa has operated long and intensely, it turns the person concerned into a sexual neurasthenic, whose potency, too, has been impaired; the intensity of the cause is paralleled by a lifelong persistence of the condition. Further evidence of the causal connection lies in the fact that a sexual neurasthenic is always a general neurasthenic at the same time.

If the noxa has not been sufficiently intense, it will have (in accordance with the formula given above) an effect on the patient's disposition; so that later, if provoking factors supervene, it will produce neurasthenia, which
[181] those factors alone would not have produced. Intellectual work – cerebral neurasthenia; normal sexual activity – spinal neurasthenia, etc.

1 [This aetiological formula was much elaborated by Freud in his second paper on anxiety neurosis (1895*f*), *RSE*, **3**, 119 ff.]

2 [The inverted commas are unexplained.]

3 [The fullest account of Freud's views on masturbation can be found in his contribution to a discussion on the subject in the Vienna Psychoanalytical Society (1912*f*), ibid., **12**. A final comment appears in an entry in a notebook written at the very end of his life, in August, 1938; (1941*f*), ibid., **23**, 275. A list of other references is given in the Editors' Note to the discussion of 1912; ibid., **12**, 237 f.]

In intermediate cases we find the neurasthenia of youth, which typically begins with and runs its course accompanied by dyspepsia, etc., and which terminates at marriage.

The second noxa, which affects men at a later age, makes its impact on a nervous system which is either intact or which has been disposed to neurasthenia through masturbation. The question is whether it can lead to detrimental results even in the former case; probably it can. Its effect is manifest in the second case, where it revives the neurasthenia of youth and creates new symptoms. This second noxa is *onanismus conjugalis* – incomplete coition in order to prevent conception. In the case of men all the methods of achieving this seem to fall into line: they operate with varying intensity according to the subject's earlier disposition, but do not actually differ qualitatively. Even normal coition is not tolerated by those with a strong disposition or by chronic neurasthenics; and beyond this, intolerance of the condom, of extra-vaginal coition and of *coitus interruptus* take their toll. A healthy man will tolerate all of these for quite a long time, but even so not indefinitely. After a certain time he behaves like the disposed subject. His only advantage over the masturbator is the privilege of a longer latency or the fact that on every occasion he needs a provoking cause. Here *coitus interruptus* proves to be the main noxa and produces its characteristic effect even in non-disposed subjects.

Neurasthenia in females. Normally, girls are sound and not neurasthenic; and this is true as well of young married women, in spite of all the sexual traumas of this period of life. In comparatively rare cases neurasthenia appears in married women and in older unmarried ones in its pure form; it is then to be regarded as having arisen spontaneously and in the same manner [as in men]. Far more often neurasthenia in a married woman is derived from neurasthenia in a man or is produced simultaneously. In that case there is almost always an admixture of hysteria and we have the common mixed neurosis of women.

The *mixed neurosis* of women is derived from neurasthenia in men in all those not infrequent cases in which the man, being a sexual neurasthenic, suffers from impaired potency. The admixture of hysteria results directly from the *holding back* of the excitation [*Erregung*][T] of the act. The poorer the man's potency, the more the woman's hysteria predominates; so that in reality a sexually neurasthenic man makes his wife not so much [182] neurasthenic as hysterical.

This neurosis arises, with neurasthenia in males, during the second onset of sexual noxae, which is of far greater significance for a woman, assuming that she is sound. Thus we come across far more neurotic men during the first decade of puberty and far more neurotic women during the second. In the latter case this is the result of the noxae due to the prevention of conception. It is not easy to arrange them in order and in general none of them should be regarded as entirely innocuous to women; so that even in the most favourable case (a condom) women, being the more exacting partners, will scarcely escape slight neurasthenia. A great deal will obviously depend on the two dispositions: whether (1) she herself was neurasthenic before marriage or whether (2) she was made hysterico-neurasthenic during the period of free intercourse [without contraceptive devices].

II. *Anxiety neurosis*.[1] Every case of neurasthenia is no doubt marked by a certain lowering of self-confidence, by pessimistic expectation and an inclination to distressing antithetic ideas.[2] But the question is whether the prominent emergence of this factor [anxiety], without the other symptoms being specially developed, should not be detached[3] as an independent 'anxiety neurosis', especially as this is to be met with no less frequently in hysteria than in neurasthenia.

Anxiety neurosis appears in two forms: as a *chronic state* and as an *attack of anxiety*. The two may readily be combined: and an anxiety attack never occurs without chronic symptoms. Anxiety attacks are commoner in the forms connected with hysteria – more frequently, therefore, in women. The chronic symptoms are commoner in neurasthenic men.

The chronic symptoms are: (1) anxiety relating to the body (hypochondria); (2) anxiety relating to the functioning of the body (agoraphobia, claustrophobia, giddiness on heights); (3) anxiety relating to decisions and memory – i.e. one's own idea of one's psychical functioning – (*folie du doute*, obsessive brooding [*Grübelzwang*][T], etc.). So far, I have found no occasion for not treating these symptoms as equivalent. Again, the question is (1) to what extent this condition emerges in hereditary cases, without any sexual noxa, (2) whether it is released in hereditary cases by

Zwang [183]

1 ['*Angstneurose*'. This seems to be the first datable use of the term; but it had already appeared in Draft A, p. 205 above. Some remarks on the word's history are given in (1895*b*), *RSE*, **3**, 82 *n*. 1.]

2 [These were discussed by Freud in 'A Case of Successful Treatment by Hypnotism' (1892–93*a*), published just before this was written (p. 148 ff. above).]

3 [This word ('*abtrennen*' in the original) appears in the full title of the first paper on anxiety neurosis (1895*b*). Much of the symptomatology of the neurosis in that paper is already in this draft. But the underlying theory only emerges in Draft E, p. 217 ff. below.]

any chance sexual noxa, (3) whether it supervenes as an intensification in common neurasthenia. There is no question but that it is acquired, and especially by men and women in marriage, during the second period of sexual noxae, through *coitus interruptus*. I do not believe that disposition owing to earlier neurasthenia is necessary for this; but where disposition is lacking, latency is longer. The causal formula is the same as in neurasthenia [p. 208 above].

The rarer cases of anxiety neurosis outside marriage are met with especially in men. They turn out to be cases of *congressus interruptus* in which the man is strongly involved psychically with women whose well-being is a matter of concern to him. This procedure in these conditions is a greater noxa for a man than *coitus interruptus* in marriage, for this is often corrected, as it were, by normal coitus outside marriage.

I must look upon *periodic depression*, an attack of anxiety lasting for weeks or months, as a third form of anxiety neurosis. This, in contrast to melancholia proper, almost always has an apparently rational connection with a psychical trauma. The latter is, however, only the provoking cause. Moreover, this periodic depression is without psychical [sexual] anaesthesia, which is characteristic of melancholia [p. 228 below].

I have been able to trace back a number of such cases to *coitus interruptus*; their onset was a late one, during marriage, after the birth of the last child. In a case of tormenting hypochondria which began at puberty, I was able to prove an assault in the eighth year of life. Another case from childhood turned out to be a hysterical reaction to a masturbatory assault. Thus I cannot tell whether we have here truly hereditary forms without a sexual cause; and on the other hand I cannot tell whether *coitus interruptus* alone is to be blamed here, whether hereditary disposition can always be dispensed with.

I will omit occupational neuroses, since, as I have told you, changes in the muscular parts have been demonstrated in them.

CONCLUSIONS

It follows from what I have said that neuroses are entirely preventable as well as entirely incurable. The physician's task is wholly shifted on to prophylaxis.

The first part of this task, the prevention of the sexual noxa of the first [184]
period, coincides with prophylaxis against syphilis and gonorrhoea, since they are the noxae which threaten anyone who gives up

masturbation. The only alternative would be free sexual intercourse between young men and respectable girls[t]; but this could only be adopted if there were innocuous methods of preventing conception. Otherwise, the alternatives are: masturbation, neurasthenia in the male, hystero-neurasthenia in the female, or syphilis in the male, syphilis in the next generation, gonorrhoea in the male, gonorrhoea and sterility in the female.

The same problem – an innocuous means of controlling conception – is set by the *sexual* trauma of the second period; since the condom provides neither a safe solution nor one acceptable to someone who is already neurasthenic.[1]

In the absence of such a solution, society appears doomed to fall victim to incurable neuroses, which reduce the enjoyment of life to a minimum, destroy the marriage relation and bring hereditary ruin on the whole coming generation. The lower strata of society know nothing of Malthusianism, but they are in full pursuit, and in the course of things will reach the same point and fall victim to the same fatality.

Thus the physician is faced with a problem whose solution is worthy of all his efforts.[2]

. . . . . .

LETTER 14[3]

. . . Things become more and more complicated as confirmation comes in. Yesterday, for instance, I saw four new cases whose aetiology, as shown by the chronological data, could only be *coitus interruptus*. It may perhaps amuse you if I give a short account of them. They are far from being uniform.

(1) Woman, aged 41; children, 16, 14, 11 and 7. Nervous trouble for the last 12 years; well during pregnancy; recurrence afterwards; not made worse by the last pregnancy. Attacks of giddiness with feeling of weakness,
[185] agoraphobia, *anxious* expectation, no trace of neurasthenia, little hysteria. Aetiology confirmed: simple [anxiety neurosis].

(2) Woman, aged 24; children, 4 and 2. Since the spring of '93 attacks of pain at night (from back to sternum) with insomnia; otherwise

1 [Freud often expressed this view later. See, for instance, his paper on the sexual aetiology of the neuroses (1898*a*), *RSE*, **3**, 271.]

2 [Draft C (undated), which follows this one in the *Anfänge*, is in fact a letter, dealing in the main with a paper by Fliess. It is omitted here.]

3 [Dated Vienna, October 6, 1893.]

nothing; well during the day. Husband a commercial traveller; was at home for some time during the spring and just now. In the summer, while the husband was away, she was perfectly well. *Coitus interruptus* and great fear of having children. Hysteria, therefore.

(3) Man, aged 42; children, 17, 16 and 13. Well till a year ago.[1] Then, on his father's death, sudden attack of anxiety with heart failure, hypochondriacal fears of cancer of the tongue; several months later a second attack, with cyanosis, intermittent pulse, fear of death, etc.; since then weakness, vertigo, agoraphobia, some dyspepsia. This is a case of pure anxiety neurosis accompanied by heart symptoms, after emotion; whereas *coitus interruptus* was apparently tolerated easily for ten years.[2]

(4) Man, aged 34. Loss of appetite for the last three years; dyspepsia for the last year, with loss of 20 kilos, constipation. When these ceased, violent intracranial pressure when a sirocco was blowing;[3] attacks of weakness with associated sensations, hysteriform clonic spasms. In this case, therefore, neurasthenia predominates. One child, aged 5. Since then *coitus interruptus* owing to wife's illness. At about the same time as his recovery from dyspepsia, normal intercourse was resumed.

In view of these reactions to the same noxa, it calls for courage to insist on the specific nature, in my sense, of its effects. And yet it must be so; and there are certain points to go upon even in these four cases (simple anxiety neurosis – simple hysteria – anxiety neurosis with heart symptoms – neurasthenia with hysteria).

In (1), a very intelligent woman, there was no fear of having children; she has a simple anxiety neurosis.

In (2), a nice, stupid young woman, the anxiety was highly developed; after a short while she had hysteria for the first time[t].

Case (3), with anxiety neurosis[4] and heart symptoms, was a very potent man, who was a great smoker.

Case (4), on the contrary, was (without having masturbated) only moderately potent – frigid. [186]

. . . . . .

1 ['six years ago' in the *SE*; due to an error in the *Anf.* transcription.]

2 [This case was discussed by Freud, with some further details, in his first and second papers on anxiety neurosis (1895*b* and 1895*f*), *RSE*, **3**, 94 f. and 113.]

3 [Cf. Draft I, p. 242 below.]

4 ['Neurosis' is omitted in *Anfänge*, 89.]

DRAFT D[1]
ON THE AETIOLOGY AND THEORY OF THE MAJOR NEUROSES

I. CLASSIFICATION

Introduction. Historical. Gradual differentiation of the neuroses. The course of development of my own views.

A. *Morphology of the Neuroses*

(1) Neurasthenia and the pseudo-neurasthenias.
(2) Anxiety neurosis.
(3) Obsessional neurosis [*Zwangsneurose*].
(4) Hysteria.
(5) Melancholia, Mania.
(6) The mixed neuroses.
(7) Ramifications of the neuroses and transitions to the normal.

B. *Aetiology of the Neuroses* (provisionally restricted to the acquired neuroses)

(1) Aetiology of neurasthenia – Type of congenital neurasthenia.
(2) Aetiology of anxiety neurosis.
(3) of obsessional neurosis and hysteria.
(4) of melancholia.
(5) of the mixed neuroses.
(6) The basic aetiological formula [p. 208 above]. – The thesis of specificity [of aetiology]; the analysis of the medley of neuroses.
(7) The sexual factors in their aetiological significance.
(8) Examination of patients.
(9) Objections and proofs.
(10) Behaviour of asexual people.[2]

C. *Aetiology and Heredity*

[187] The hereditary types. – Relation of aetiology to degeneracy, to the psychoses and to disposition.

1 [Undated. Assigned provisionally by the editors of *Anf*. to a date shortly previous to that of Letter 18, of May 21, 1894, where it is perhaps alluded to (in a passage not printed here). This appears to be the skeleton outline of a book that was never written.]

2 [This sentence was erroneously italicized in the *SE*.]

II. THEORY

D. *Points of Contact with the Theory of Constancy*[1]

Internal and external increase of stimulus; constant and ephemeral excitation. – Summation a characteristic of internal excitation.[2] – Specific reaction.[3] – Formulation and exposition of the theory of constancy. – Intercalation of the ego [*Ich*][T], with storing up of excitation.[4]

E. *The Sexual Process in the Light of the Theory of Constancy*

Path taken by the excitation in the male and the female sexual process. – Path taken by the excitation in the presence of aetiologically operative sexual noxae. – Theory of a sexual substance.[5] – The sexual schematic diagram.[6]

F. *Mechanism of the Neuroses*

The neuroses as disturbances of equilibrium owing to increased difficulty in discharge [*Abfuhr*][T]. – Attempts at adjustment, limited in their efficiency. – Mechanism of the different neuroses in relation to their sexual aetiology. – Affects and neuroses.

abführen

G. *Parallel between the Neuroses of Sexuality and Hunger*

H. *Summary of the Theory of Constancy and the Theory of Sexuality and the Neuroses*

Place of the neuroses in pathology; factors to which they are subject; laws governing their combination. – Psychical inadequacy, development, degeneracy, etc.

1 [Cf. 'Project', Part I, Section 1 (p. 320 below).]

2 [Cf. ibid., Section 10 (pp. 340–1 below).]

3 [Cf. ibid., Section 1 (p. 321 below).]

4 [Cf. ibid., Section 14 (pp. 347–8 below).]

5 [This is an early allusion to Freud's theory of the chemical basis of sexuality. The whole question was very closely associated with Fliess in Freud's mind, as is shown by many passages in these letters. See a footnote to the 'Project', p. 346 *n.* 2 below. This sentence was underlined in the original MS., but apparently by someone other than the author (Fliess?).]

6 [This appears below, on p. 230, and the other contents of this paragraph are also elaborated in Draft G.]

LETTER 18[1]

[188] . . . There are still a hundred gaps, large and small, in my ideas about the neuroses; but I am getting closer to a comprehensive view and to some general lines of approach. I know three mechanisms: transformation of affect (conversion hysteria), displacement of affect [*Affektverschiebung*][T] (obsessions) and (3) exchange of affect (anxiety neurosis and melancholia). In every case what seems to undergo these alterations is sexual excitation, but the impetus to them is not in every case something sexual. That is to say, in every case in which neuroses are acquired, they are acquired owing to disturbances of sexual life; but there are people in whom the behaviour of their sexual affects is disturbed hereditarily, and they develop the corresponding forms of hereditary neuroses. The most general aspects from which I can classify the neuroses are the four following:

Verschiebung

(1) Degeneracy.
(2) Senility.
(3) Conflict.
(4) Conflagration.

What do those mean?

Degeneracy means the innately abnormal behaviour of the sexual affects; so that the processes of conversion, displacement and transformation into anxiety occur in proportion as the sexual affects play a part in the course of life.

Senility is clear. It is, as it were, a degeneracy normally acquired in old age.[2]

Conflict coincides with my conception of defence [*Abwehr*][T]; it comprises the cases of acquired neurosis in people who are not hereditarily abnormal. What is fended off [*Abgewehrte*] is always sexuality.

Conflagration is a new conception. It means what may be called acute degeneration (e.g. in severe intoxications, in fevers, in the preliminary stage of general paralysis) – catastrophes, that is to say, in which there are disturbances of the sexual affects without sexual precipitating causes. Perhaps traumatic neuroses might be approached from this point.[3]

1 [Dated Vienna, May 21, 1894. – This was written halfway through the publication of the first paper on 'The Neuropsychoses of Defence' (1894*a*), *RSE*, **3**, 43 ff.]

2 [Senescence is referred to in the first paper on anxiety neurosis (1895*b*), ibid., **3**, 91 and 98.]

3 [Conflagration seems never to be mentioned again.]

The core and mainstay of the whole business remains, of course, the fact that, as a result of particular sexual noxae, even healthy people can acquire the different forms of neurosis. The bridge to a wider view [189]
[*Auffassung*][T] is afforded by the fact that, where a neurosis develops without a sexual noxa, a similar disturbance of the sexual affects can be shown to have been present from the first. 'Sexual affect' is, of course, taken in the broadest sense, as an excitation of definite quantity.[1]

I might bring you my latest example in support of this thesis:

A man, aged 42, strong and handsome, suddenly developed a neurasthenic dyspepsia at the age of 30 with a loss of 25 kilos, and since then has lived in a reduced and neurasthenic state. At the time at which this occurred, incidentally, he was engaged to be married and was emotionally disturbed by his fiancée's illness. Apart from this, however, there were no sexual noxae. He masturbated, perhaps only for a year, from 16 to 17; from 17 onwards he had normal intercourse; scarcely ever *coitus interruptus*; no excesses, no abstinence. He himself attributes the cause to the strain he put on his constitution till the age of 30: to his having worked, drunk and smoked a great deal and led an irregular life. But this strong man, subject to [only] stock noxae, was *never* (never from 17 to 30) properly potent: he could never carry out coitus more than once at a time; he always emitted hurriedly, never made full use of his [initial] successes with women, never found his way into the vagina quickly. What was the origin of this limitation? I cannot tell. But it is remarkable that it was present precisely in him. By the way, I have treated two of his sisters for neuroses; one of them is among my most successful cures of neurasthenic dyspepsia.

. . . . . .

DRAFT E[2]
HOW ANXIETY ORIGINATES

With an unerring hand you have raised the question at the point which I feel is the weak one. All I know about it is this:

1 [The concept of 'quantity' is given lengthy discussion in the 'Project', p. 319 below.]

2 [Undated. The editors of *Anf.* assign it to June, 1894, but without much conviction. It must in any case have been written not long before the first paper on anxiety neurosis (1895*b*), which was published on January 15, 1895, and of which it is a fairly complete preliminary sketch. – The present draft and several of the writings which follow are largely concerned with Freud's theory of the transformation of accumulated sexual tension into anxiety, and with his explanation that this is due to a failure in the discharge of the tension along *psychical* paths.]

[190] It quickly became clear to me that the anxiety of my neurotic patients had a great deal to do with sexuality; and in particular it struck me with what certainty *coitus interruptus* practised on a woman leads to anxiety neurosis. I then began by following various false scents. I thought that the anxiety from which the patients suffer should be looked on as a continuation of the anxiety felt during the sexual act – that is to say, that it was in reality a *hysterical* symptom. Indeed, the connections between anxiety neurosis and hysteria are obvious enough. Two things might give rise to the feeling of anxiety in *coitus interruptus*: in the woman, a fear of becoming pregnant, in the man worry that his [contraceptive] device might fail. I then convinced myself from a number of cases that anxiety neurosis also appeared where there was no question of these two factors, where it was basically of no importance to the people concerned whether they had a baby. Thus the anxiety of anxiety neurosis was not a continued, recollected, *hysterical* one.[1]

A second extremely important point became established for me from the following observation. Anxiety neurosis affects women who are anaesthetic in coitus just as much as sensitive ones. This is most remarkable, but it can only mean that the source of the anxiety is not to be looked for in the psychical sphere. It must accordingly lie in the physical sphere: it is a physical factor in sexual life that produces anxiety. But what factor?

With this aim in view, I brought together the cases in which I found anxiety arising from a sexual cause. They seemed at first to be quite heterogeneous:

(1) Anxiety in *virginal* people (sexual observations and information, foreshadowings of sexual life); confirmed by numerous instances of both sexes, predominantly female. Not infrequently there is a hint at an intermediate link – a sensation like an erection arising in the genitals.

(2) Anxiety in *intentionally abstinent* people, *prudes* (a type of neuropath), men and women characterized by pedantry and a feeling for cleanliness, who regard everything sexual as horrible. The same people tend to work their anxiety over into phobias, obsessional actions [*Zwangshandlungen*], *folie du doute*.[2]

[191] (3) Anxiety of *necessarily abstinent* people, women who are neglected by their husbands or are not satisfied on account of lack of potency.

1 [The MS. reads: '*Also eine fortgesetzte, erinnerte, hysterische Angst war die der Angstneurose nicht*.' *Anf*., 99, omits '*der*', giving the sense: 'Thus anxiety neurosis was not a . . . hysterical anxiety.']

2 [The connection between cleanliness, pedantry and obsessions was to be greatly emphasized and expanded later. Cf. 'Character and Anal Erotism' (1908*b*), *RSE*, **9**, 151–2.]

This form of anxiety neurosis can certainly be acquired, and, owing to subsidiary circumstances, is often combined with neurasthenia.

(4) Anxiety of women living in *coitus interruptus*, or, what is similar, of women whose husbands suffer from *ejaculatio praecox* – of people, therefore, who do not obtain satisfaction from physical stimulation.

(5) Anxiety of men practising *coitus interruptus*, even more of men who excite themselves in various ways and do not employ their erection for coitus.

(6) Anxiety of men *who go beyond their desire or strength*, older people whose potency is diminishing,[1] but who nevertheless forcibly bring about coitus.

(7) Anxiety of men who abstain on occasion: of youngish men who have married older women, by whom they are in fact disgusted, or of *neurasthenics* who have been diverted from masturbation by intellectual occupation without making up for it by coitus, or of men whose potency is beginning to grow weak and who abstain in marriage on account of sensations *post coitum* [cf. p. 227 *n*. 1 below].

In the remaining cases the connection between the anxiety and sexual life was not obvious. (It could be established theoretically.)

How are all these separate cases to be brought together? What recurs in them most frequently is abstinence. Taught by the fact that even anaesthetic women are subject to anxiety after *coitus interruptus*, one is inclined to say that it is a question of a physical accumulation of excitation – that is, *an accumulation of physical sexual tension*. The accumulation is the consequence of discharge being prevented. Thus anxiety neurosis is a neurosis of damming up, like hysteria; hence their similarity. And since no anxiety at all is contained in what is accumulated, the position is expressed by saying that *anxiety* has arisen by *transformation* out of the accumulated sexual tension.[2]

Some knowledge arrived at simultaneously about the mechanism of melancholia may be interpolated here. Quite particularly often melancholics have been *anaesthetic*.[3] They have no need for coitus (and no sensation in connection with it). But they have a great longing for love in [192]

1 [The MS. reads: '*älterer Leute, deren Potenz nachlässt*'. This clause is omitted in *Anf*., 100.]

2 [The word '*sexualen*' is omitted from the end of this sentence in *Anf*., 100. – This was the view of the origin of anxiety, perhaps first stated here, which Freud held till very late in life. An account of his changing opinions on the subject can be found in the Editors' Introduction to *Inhibitions, Symptoms and Anxiety* (1926*d*), *RSE*, **20**, 70 ff.]

3 [This whole question is developed in Draft G, p. 228 ff. below. – Freud often uses the term 'melancholia' where modern psychiatry would speak of 'depression'.]

its psychical form – one might say, psychical erotic tension. Where this accumulates and remains unsatisfied, melancholia develops. Here, then, we should have the counterpart to anxiety neurosis. Where physical sexual tension accumulates – anxiety neurosis. Where psychical sexual tension accumulates – melancholia.

But why does this transformation into anxiety occur when there is an accumulation? At this point we ought to enter into the normal mechanism for dealing with accumulated tension. What we are concerned with here is the second case – the case of endogenous excitation [*Erregung*]. Things are simpler in the case of exogenous excitation. The source of excitation is outside and sends into the psyche an accretion of excitation which is dealt with according to its quantity. For that purpose any reaction suffices which diminishes the psychical excitation by the same quantum. [Cf. footnote 1, p. 199 above.]

But it is otherwise with endogenous tension, the source of which lies
Trieb in one's own body (hunger, thirst, the sexual drive [*Sexualtrieb*][T]). In this case only *specific* reactions are of use[1] – reactions which prevent the further occurrence of the excitation in the end-organs concerned, whether those reactions are attainable with a large or small expenditure [of energy]. Here we may picture the endogenous tension as growing either continuously or discontinuously, but in any case as only being noticed when it has reached a certain *threshold*. It is only above this threshold that it is turned to account *psychically*, that it enters into relation with certain groups of ideas,[2] which thereupon set about producing the specific remedies. Thus physical sexual tension above a certain value arouses psychical libido,[3] which then leads to coitus, etc. If the specific reaction fails to ensue, the physico-psychical tension (the sexual affect) increases immeasurably. It becomes a disturbance, but there is still no
[193] ground for its transformation. In anxiety neurosis, however, such a transformation does occur, and this suggests the idea that there things go wrong in the following way. The physical tension increases, reaches the threshold value at which it can arouse psychical affect; but for some reasons the psychical linkage offered to it remains insufficient: a *sexual affect* cannot be formed, because there is something lacking in the

1 [Cf. 'Project', Part I, Sections 1 and 11 (pp. 321 and 342 f. below).]

2 [The concept of 'psychical groups' is commented on in an Editors' footnote to the first paper on the neuropsychoses of defence (1894*a*), *RSE*, **3**, 43 f. *n.* 2.]

3 [This is possibly Freud's earliest recorded use of the term 'libido'. See an Editors' footnote to the first paper on anxiety neurosis (1895*b*), ibid., **3**, 91 *n.* 2.]

psychical determinants. Accordingly, the physical tension, not being psychically bound, is transformed into – anxiety.[1]

If we accept the theory so far, we shall have to insist that in anxiety neurosis there must be a deficit to be noted in sexual affect, in *psychical libido*. And this is confirmed by observation. If this connection is put before women patients, they are always indignant and declare that on the contrary they now have no desire whatever, etc. Men patients often confirm it as an observation that since suffering from anxiety they have felt no sexual desire.

We will now see whether this mechanism agrees with the different cases enumerated above.

(1) *Virginal anxiety*. Here the field of ideas which ought to take up the physical tension is not yet present, or is only insufficiently present; and there is in addition a psychical refusal which is a secondary result of education [*Erziehungsresultat*][T]. This fits in very well. *Erziehung*

(2) *Anxiety of prudes*. Here what we have is defence – outright psychical rejection, which makes any working over of the sexual tension impossible. Here too we have the case of the numerous obsessions. This fits in very well.

(3) *Anxiety of necessitated abstinence*. This is essentially the same; for women of this kind mostly create a psychical rejection so as to avoid temptation. Here the rejection is a contingent one, in (2) it is a fundamental matter.

(4) *Anxiety in women from coitus interruptus*. Here the mechanism is simpler. It is a question of endogenous excitation which does not originate [spontaneously] but is induced, but not in an amount sufficient to be able to arouse psychical affect. An alienation[2] is artificially brought about [194] between the physico-sexual act and its psychical working over. If afterwards the endogenous tension increases further on its own account, it cannot be worked over and generates anxiety. Here libido can be present, but not at the same time as anxiety.[3] Thus here *psychical rejection* is

1 [The word 'physical', in the last sentence, is omitted in *Anf*., 101. – It seems doubtful whether the term 'bound' (making a first appearance here) is being used in the technical sense in which Freud used it later in the 'Project' (e.g. p. 360 below). – It is to be noticed that 'libido' is regarded in these early writings as essentially 'psychical'; though it is not yet clear whether that still means the same as 'conscious'. Cf. the further development in Draft G below, and some remarks in the Editors' Note to the first paper on anxiety neurosis (1895*b*), *RSE*, **3**, 80.]

2 ['*Entfremdung*.' The word is also used in the first paper on anxiety neurosis, ibid., **3**, 99.]

3 ['*Hier kann Libido enthalten sein, aber nicht gleichzeitig mit Angst*.' This sentence is omitted in *Anf*., 102.]

followed by *psychical alienation*; tension of endogenous origin is followed by induced tension.

(5) *Anxiety in men from coitus interruptus or reservatus*. The case of *coitus reservatus* is the clearer; *coitus interruptus* may in part be regarded as subsumed under it. It is a question once again of psychical diversion, for attention is directed to another aim and is kept away from the working over of physical tension. The explanation of *coitus interruptus*, however, probably stands in need of improvement.

(6) *Anxiety in diminishing potency or insufficient libido*. Insofar as this is not the transformation of physical tension into anxiety owing to *senility*, it is to be explained by the fact that insufficient psychical desire can be summoned up for the particular act.

(7) *Anxiety in men from disgust, or in abstinent neurasthenics*. The former calls for no fresh explanation; the latter is perhaps a specially attenuated form of anxiety neurosis, for as a rule this occurs[t] properly only in potent men. It may be that the neurasthenic nervous system cannot tolerate an accumulation of physical tension, since masturbation involves becoming accustomed to frequent and complete absence of tension.

On the whole the agreement is not so bad. Where there is an abundant development of physical sexual tension but this cannot be turned into affect by psychical working over – because of insufficient development of psychical sexuality or because of the attempted suppression of the latter (defence), or of its falling into decay, or because of habitual alienation between physical and psychical sexuality – the sexual tension is transformed into *anxiety*. Thus a part is played in this by the accumulation of physical tension and the prevention of discharge in the psychical direction.

But why does the transformation take place precisely into anxiety? Anxiety is the sensation of the accumulation of another endogenous stimulus, the stimulus to breathing, a stimulus which is incapable of being worked over psychically apart from this; anxiety might therefore
[195] be employed for accumulated physical tension in general. Furthermore, if we examine the symptoms of anxiety neurosis more closely, we find in it the disjointed pieces of a major anxiety attack: viz. simple dyspnoea, simple palpitations, simple feelings of anxiety and a combination of these. Looked at more precisely, these are the paths of innervation which the psychosexual tension ordinarily traverses even when it is about to be worked over psychically. The dyspnoea and palpitations

belong to coitus;[1] and, while ordinarily they are employed only as subsidiary paths of discharge, here they serve, so to speak, as the only outlets for the excitation. There is a kind of *conversion* in anxiety neurosis just as there is in hysteria (another instance of their similarity [p. 218 above]); but in hysteria it is *psychical* excitation that takes a wrong path exclusively into the somatic field, whereas here it is a *physical* tension, which cannot enter the psychical field and therefore remains on the physical path. The two are combined extremely often.

That is as far as I have got today. The gaps need filling in badly. I think it is incomplete, I lack something; but I believe the foundation is right. Of course it is absolutely unripe for publicity. Suggestions, amplifications, indeed refutations and explanations will be received *most* gratefully.

. . . . . .

DRAFT F
COLLECTION III[2]

18 Aug. 94
No. 1
Herr K., aged 24 Anxiety neurosis: hered. disp.

Father treated for senile melancholia; sister, O., good case of complicated anxiety neurosis, thoroughly analysed; all the K.s neurotic and temperamentally gifted. A cousin of Dr K. in Bordeaux. – In good health till recently; has slept badly for the last 9 months; in February and March woke frequently with night terrors and palpitations; gradually increasing general excitability; intermission owing to army manoeuvres, which did him a great deal of good. Three weeks ago in the evening a [196]
sudden attack of anxiety with no content, with a feeling of congestion from his chest up to his head. Interpreted [by him to mean that] something dreadful was bound to happen; no accompanying oppression and only slight palpitations. Similar attacks afterwards in daytime as well, at his midday meal. Two weeks ago he consulted a doctor; improved on bromide, [condition] still continues, but sleeps well. In addition during the last two weeks short attacks of deep depression, resembling complete apathy, lasting barely a few

1 [Cf. some remarks on this in the Editors' Introduction to *Inhibitions, Symptoms and Anxiety* (1926*d*), *RSE*, **20**, 74.]

2 [These two case histories, which are dated August 18 and 20, 1894, were contained in two successive letters. The heading is unexplained.]

minutes. Improved here in R[eichenau]. Besides this, attacks of pressure at the back of the head.

He himself began with [volunteering] sexual information. A year ago he fell in love with a girl who was a flirt; a great shock when he heard she was engaged to someone else. No longer in love now. – Attaches little importance to it. – He went on: he masturbated between 13 and 16 or 17 (seduced at school) to a moderate extent, he said. Moderate in sexual intercourse; has used a condom for the last 2½ years for fear of infection; often feels limp after it. He described this kind of intercourse as forced. Notices that his libido has quite significantly[1] diminished for about a year. Was very much excited sexually in his relations with the girl (without touching her, etc.). His first attack at night (February) was two days after coitus; his first anxiety attack was after coitus on the same evening; since then (three weeks) abstinent – a quiet, mild-mannered and in other ways healthy man.

18 Aug. 94
Discussion of No. 1

If we attempt to interpret the case of K., one thing in particular strikes us. The man has a hereditary disposition: his father suffers from melancholia, perhaps anxious melancholia; his sister has a typical anxiety neurosis; I am intimately acquainted with it, but otherwise I should certainly have described it as acquired. This gives ground for thought on their heredity. There is probably only a 'disposition' in the K. family (a tendency to fall ill with greater certainty and more seriously in response to the typical aetiology) and not 'degeneracy'. We may therefore expect that in Herr K.'s case the slight anxiety neurosis developed from a slight aetiology. Where is it to be looked for without prejudice?

It seems to me in the first place that it is a question of an *enfeebled* condition of sexuality. The man's libido has been diminishing for some time; the preparations for using a condom are enough to make him feel
[197] that the whole act is something forced on him and his enjoyment of it something he was persuaded into. This is no doubt the nub of the whole business. After coitus he sometimes feels limp; he notices this, as he says, and then, two days after a coitus or, as the case may be, on the next evening, he has his first attacks of anxiety.

The concurrence of reduced libido and anxiety neurosis fits in with my theory without difficulty. There is a weakness in the psychical mastery of

1 ['*etwa sehr*.' The word '*etwa*' ('quite') was overlooked in the *Anf*. transcription and therefore in the *SE*.]

the somatic sexual excitation. This weakness has been present for some time and makes it possible for anxiety to appear if there is an incidental increase in somatic excitation.

How was this psychical enfeeblement acquired? There is not much to be got out of his masturbation in his youth; it would certainly not have had such results, especially as it does not seem to have exceeded the usual amount. His relations with the girl, which excited him very much sensually, seem far better calculated to produce a disturbance in the required direction; in fact, the case approaches the conditions in the familiar neuroses of men during long engagements. But above all, it cannot be disputed that the fear of infection and the decision to use a condom laid the foundation for what I have described as the factor of alienation between the somatic and the psychical [p. 221 f. above]. The effect would be the same as in the case of *coitus interruptus* with men. In short, Herr K. brought psychical sexual weakness on himself because he spoilt coitus for himself, and, his physical health and production of sexual stimuli being unimpaired, the situation gave rise to the generation of anxiety. We may add that his readiness to take precautions, instead of finding adequate satisfaction in a secure relationship, points to a sexuality which was from the first of no great strength. The man has a hereditary disposition; the aetiology that can be found in his case, though it is qualitatively important, would be tolerated as harmless by a healthy – that is, by a vigorous – man.

An interesting feature of this case is the appearance of a typically melancholic mood in attacks of short duration. This must be of theoretical importance for anxiety neurosis due to alienation; for the moment I can only make a note of it.

20 Aug. 94
No. 2.
Herr von F., Budapest, aged 44

A healthy man physically, he complains that 'he is losing his liveliness and zest, in a way that is not natural in a man of his age'. This state – in [198]
which everything seems indifferent to him, in which he finds his work a burden and feels peevish and limp – is accompanied by severe pressure on the top and also the back of his head. Moreover, it is regularly characterized by bad digestion – that is, by disinclination for food and by flatulence and sluggish stools. He also seems to sleep badly.

But the state is evidently intermittent. Each time it lasts for 4 or 5 days and slowly passes off. He notices from the flatulence that the nervous weakness is coming on. There are intervals of from 12 to 14 days, and he may be well for several weeks. Better periods of months' duration have even occurred. He insists that things have been like this for the last 25 years. As so often, one has to start by building up the clinical picture, for he keeps on monotonously repeating his complaints and declares that he has paid no attention to other events. Thus the indeterminate outline of the attacks forms part of the picture, as does their complete irregularity in time. He naturally puts the blame for his state on his digestion. Benedikt[1] put the diagnosis in writing: *Cephalaea cum digestione tarda*.

Organically sound; no serious worries or emotional disturbance. As regards sexuality: masturbated between the ages of 12 and 16; then very regular relations with women; he was not enormously attracted; married for the last 14 years, only two children, the last 10 years ago; in the interval and since then, only a condom and no other technique. Potency has decidedly diminished in the last few years. Coitus every 12 to 14 days or so; often, too, with long intervals. Admits that he feels limp and wretched after coitus with a condom; but not immediately afterwards, only 2 days later – or, as he puts it, he has noticed that 2 days later he gets digestive trouble. Why does he use a condom? One should not have too many children! ([He has] two.)

Discussion [of No. 2]

A mild but actually[2] very characteristic case of periodic depression, melancholia. Symptoms: apathy, inhibition [*Hemmung*][T], intracranial pressure, dyspepsia, insomnia – the picture is complete.

There is an unmistakable similarity to neurasthenia, and the aetiology is the same. I have some quite analogous cases: they are masturbators (Herr A.) and also with a hereditary taint. The von F.s from Budapest are well known to be psychopathic.[3] Thus the case is one of neurasthenic melancholia; there must be a point of contact here with the theory of neurasthenia.

It is quite possible that the starting point of a minor melancholia like
[199] this may always be an act of coitus: an exaggeration of the physiological

1 [Presumably Moritz Benedikt (1835–1920), electrotherapist and pathologist.]

2 ['*eigentlich*.' The word was overlooked in the *Anf.* transcription and therefore in the *SE*.]

3 [The term 'psychopathic' had a different meaning to what it has today – it covered the middle ground between health and mental illness.]

saying '*omne animal post coitum triste*'.[1] The time intervals would fit in. The man is improved by every course of treatment, every absence from home – that is, by every period of relief from coitus. Of course, as he says, he is faithful to his wife. The use of a condom is evidence of weak potency; being something analogous to masturbation, it is a continuous causation of his melancholia.

LETTER 21[2]

. . . I have only collected a few cases this Monday.

No. 3

Dr Z., a physician, aged 34. Has suffered for many years from organic sensitivity of the eyes: phospheum [flashes], dazzle, scotomas, etc. This has increased enormously, to the point of preventing him working, in the last four months (since the time of his marriage). *Background*: masturbation since the age of 14, apparently continued up to recent years. Marriage not consummated, much reduced potency; incidentally, divorce proceedings begun.

Clear typical case of hypochondria in a particular organ in a masturbator at periods of sexual excitation. It is interesting that medical education reaches such a shallow depth.

No. 4

Herr D., nephew of Frau A., who died a hysteric. A highly neurotic family. Aged 28. Has suffered for some weeks from lassitude, intracranial pressure, shaky knees, reduced potency, premature ejaculation, the beginnings of perversion: very young girls excite him more than mature ones.

Alleges that his potency has been capricious from the first; admits masturbation, but not too prolonged; has a period of abstinence behind him now. Before that, anxiety states in the evening.

Has he made a full confession?

. . . . . .

1 ['Every animal is sad after copulating.' Aristotle, *De generatione animalium*, I, 18 (725b).]

2 [Dated Reichenau, August 29, 1894. – It is not clear whether the numbering of these two cases is a continuation of the two in Draft F above.]

DRAFT G[1]
MELANCHOLIA[2]

I

[200] The facts before us seem to be as follows:

(A) There are striking connections between melancholia and [sexual] anaesthesia. This is borne out (1) by the finding that with many melancholics there has been a long previous history of anaesthesia, (2) by the discovery that everything that provokes anaesthesia encourages the generation of melancholia, (3) by the existence of a type of woman, very demanding psychically, in whom longing easily changes over into melancholia and who is anaesthetic.

(B) Melancholia is generated as an intensification of neurasthenia through masturbation.

(C) Melancholia appears in typical combination with severe anxiety.

(D) The type and extreme form[3] of melancholia seems to be the periodic or cyclical hereditary form.

II

In order to make anything of this material, we need some fixed points of departure. These seem to be provided by the following considerations:

(*a*) The affect corresponding to melancholia is that of mourning – that is, longing for something lost. Thus in melancholia it must be a question of a loss[4] – a loss in the life of the *drives* [*Triebleben*].

(*b*) The nutritional neurosis parallel to melancholia is anorexia. The famous *anorexia nervosa* of young girls seems to me (on careful observation) to be a melancholia where sexuality is undeveloped. The patient asserted that she had not eaten, simply because she had *no appetite*, and for no other reason. Loss of appetite – in sexual terms, loss of libido.

[201] It would not be far wrong, therefore, to start from the idea that *melancholia consists in mourning over loss of libido*.

1 [Undated. The editors of *Anf.* ascribe it (on the basis of the postmark on an envelope that apparently belongs to it) to January 7, 1895. This would make it later than the first paper on anxiety neurosis (1895*b*), with which it is connected and which was *published* on January 15, 1895.]

2 [See footnote 3, p. 219 above.]

3 [The use of extreme forms as the 'type' of a disease was a method derived by Freud from Charcot. See his Preface to the translation of Charcot's *Leçons du mardi* (1892–94*a*), p. 162 f. above.]

4 [I.e. a loss in the amount of somatic sexual excitation (see 'III' below).]

It would remain to be seen whether this formula explains the occurrence and characteristics of melancholic patients. I shall discuss this on the basis of the schematic diagram of sexuality.

III

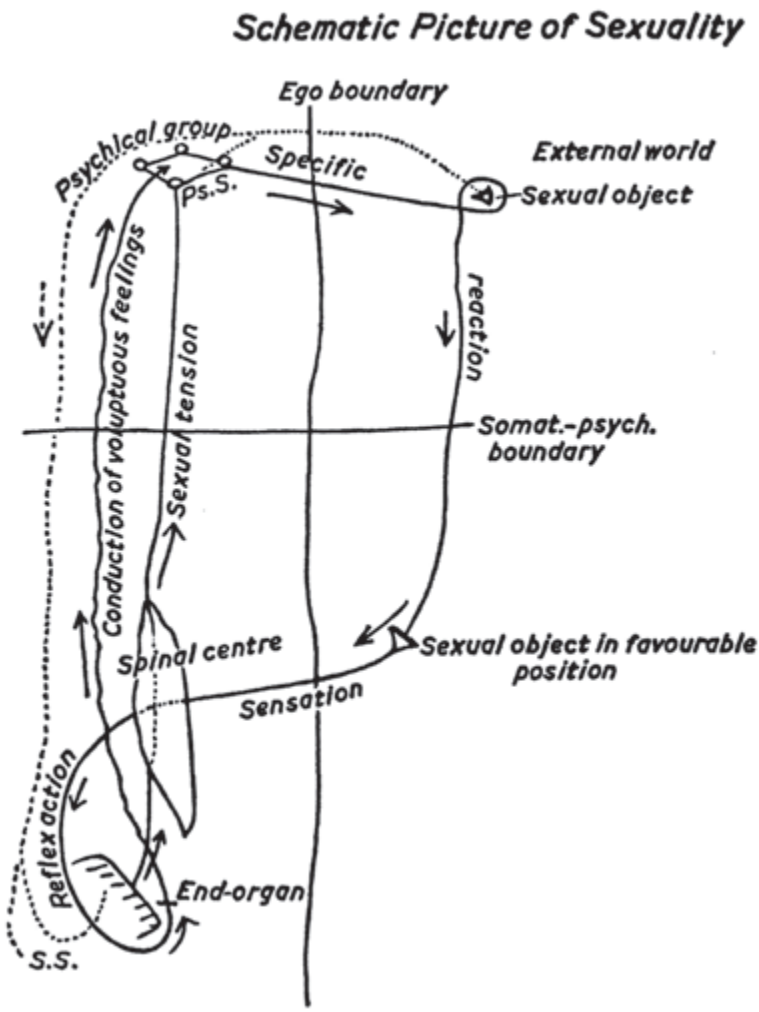
I shall now discuss, on the basis of the schematic diagram of sexuality [Fig. 1], which I have often used,[1] the conditions under which the psychical sexual group (ps. S.)[2] suffers a loss in the amount of its excitation [*Erregungsgröße*]. Here there are two possible cases: (1) if the production of s. S. (somatic sexual excitation) sinks or ceases, and (2) if the sexual tension is diverted from the ps. S. [psychical sexual group]. The first case, in which the production of s. S. [somatic sexual excitation] ceases, is probably what is characteristic of *genuine severe* melancholia proper which recurs periodically, or of cyclical melancholia, in which periods of increase and cessation of production alternate. Further, we can assume that excessive masturbation, which according to our theory leads to excessive unloading of E. (the end-organ) and thus to a low level of stimulus in E. – excessive masturbation goes on to affect the production of s. S. [somatic sexual excitation] and to bring about a lasting reduction in s. S., consequently to a weakening of the p. S. [psychical sexual group]. This is neurasthenic melancholia. The [second] case, in which sexual tension is diverted from the p. S. [psychical sexual group], while the production of s. S. [somatic sexual excitation] is not diminished, presupposes that the s. S. [somatic sexual excitation] is employed [203]
elsewhere – at the boundary [between the somatic and the psychical]. This, however, is the determinant of anxiety; and accordingly this coincides with the case of anxious melancholia, a mixed form combining anxiety neurosis and melancholia.

In this discussion, therefore, the three forms of melancholia, which must in fact be distinguished, are explained.

1 [Cf. p. 215 above. – The remarkable diagram overleaf deserves close examination. It throws light on many points not only in the present draft but in others of Freud's contemporary writings – in particular on the first paper on anxiety neurosis (1895*b*), *RSE*, **3**, 79 f. and 96 f.]

2 [I.e. the group of ideas with which the physical sexual tension enters into relation after reaching a certain threshold, and which then work over the tension and deal with it psychically (see p. 219 f. above). – Here, as elsewhere in these manuscripts, Freud makes use of numerous abbreviations. He himself does not use them uniformly and their expansion is not always easy. Thus in this passage he explains that 'ps. S.' stands for 'psychical sexual group'; but a dozen lines lower down we find 'p. S.' for what is certainly the same term, and later on 'ps. G.'. It must be pointed out that in *Anf*. the abbreviation 's. S.' is repeatedly expanded incorrectly to '*somatische Sexualspannung*' ('somatic sexual tension') instead of to '*somatische Sexualerregung*' ('somatic sexual excitation'), as Freud specifically directs.]

[202]



[Fig. 1]

[In the original all the arrows are in red, except the dotted one near the top on the extreme left.]

IV

How does it come about that anaesthesia plays this part in melancholia?

According to the schematic diagram [Fig. 1], there are the following kinds of anaesthesia.

Anaesthesia always consists, to be sure, in the omission of V. (the voluptuous feeling) which ought to be conducted into the ps. S. [psychical sexual group] after the reflex action which unloads [*entlastet*] the end-organ. The voluptuous feeling is measured by the amount of unloading.

(*a*) The E. [end-organ] is not sufficiently loaded; hence the unloading at coitus is slight and the V. [voluptuous feeling] very small: the case of frigidity.

(*b*) The pathway from sensation to the reflex action is damaged, so that the action is not sufficiently strong. If so, the unloading and the V. are also slight: the case of masturbatory anaesthesia, the anaesthesia of *coitus interruptus*, etc.

(*c*) Everything below is in order; only, V. is not admitted to the ps. G. [psychical sexual group] owing to being linked in another direction (with disgust – defence): this is hysterical anaesthesia, which is entirely analogous to hysterical anorexia (disgust).

To what extent, then, does anaesthesia encourage melancholia?

In case (*a*), of frigidity, anaesthesia is not the *cause* of melancholia but a sign of a disposition to it. This tallies with Fact A(1) mentioned at the beginning [p. 228 above]. In other cases the anaesthesia *is* the cause of the melancholia, since the ps. G. [psychical sexual group] is strengthened by the introduction of V. and weakened by its omission. (Based on general theories of the binding of excitation in the memory.)[1] Fact A(2) is thus taken into account [p. 228].

It follows from this that it is possible to be anaesthetic without being melancholic. For melancholia is related to the omission of s. S. [somatic sexual excitation] while anaesthesia is related to the omission of V. Anaesthesia is, however, a sign of or a preparation for melancholia, since the p. S. [psychical sexual group] is as much weakened by the omission of V. as by the omission of s. S. [somatic sexual excitation]. [204]

1 [This was to be discussed at length in the 'Project'. See p. 403 ff. below.]

V

The question has to be considered of how it comes about that anaesthesia is so predominantly a characteristic of women. This arises from the passive part played by them. An anaesthetic man will soon cease to undertake any coitus; a woman has no choice. Women become anaesthetic more easily because:

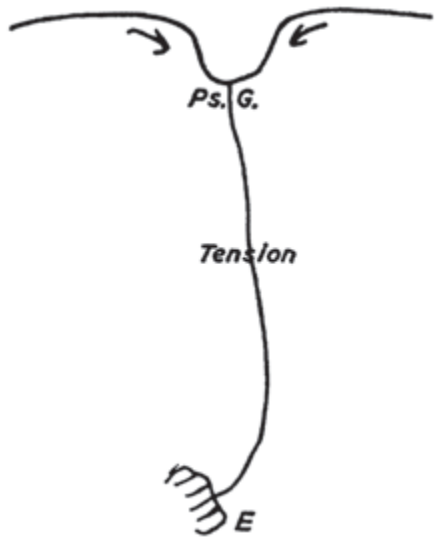
(1) their whole upbringing works in the direction of not awakening s. S. [somatic sexual excitation], but of changing all excitations which might otherwise have that effect into psychical stimuli – that is, of directing the dotted line [in the schematic diagram, Fig. 1] from the sexual object entirely into the ps. G. [psychical sexual group]. This is necessary because, if there were a vigorous s. S. [somatic sexual excitation], the ps. G. [psychical sexual group] would soon acquire such strength intermittently that, as in the case of men, it would bring the sexual object into a favourable position by means of a specific reaction [p. 220 above]. But women are required to leave out the arc of the specific reaction; instead, permanent specific actions are required of them which entice the male into the specific action. Thus sexual tension is kept low, its access to the ps. G. [psychical sexual group] so far as possible cut off and the indispensable strength of the ps. G. supplied in another way. If, now, the ps. G. gets into a state of longing, then, in view of the low level [of tension] in the E. [end-organ], that state is easily transformed into melancholia. The ps. G. in itself is capable of little resistance. Here we have the juvenile, immature type of libido, and the demanding, anaesthetic women mentioned above [Fact A(3), p. 228] merely continue this type.

(2) Women [become anaesthetic more easily than men do] because they so often approach the sexual act (marry) without love – that is, with less s. S. [somatic sexual excitation] and tension in the E. In that case they are frigid and remain so.

The low level of tension in the E. seems to contain the main disposition to melancholia. In individuals of this kind every neurosis easily takes on a melancholic stamp. Thus, whereas potent individuals easily acquire anxiety neuroses, impotent ones incline to melancholia.

VI

[205] And now, how can the effects of melancholia be explained? The best description of them: *psychical inhibition with impoverishment of drive* [*Triebverarmung*] *and pain concerning it*.

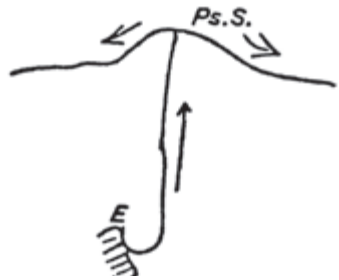


[Fig. 2]

We can imagine that, if the ps. G. [psychical sexual group] meets with a very great loss in the amount of its excitation, there may come about *an in-drawing* (as it were) *into the psychical sphere*, which produces an effect of suction upon the adjoining amounts of excitation. The associated neurons are obliged to give up their excitation, *which produces pain* [*Schmerz*][T]. [Fig. 2.] Uncoupling associations is always painful. There sets in an impoverishment in excitation (in the free store of it) – an *internal haemorrhage*, as it were – which shows itself in the other drives [206] and functions. This in-drawing operates inhibitingly, like a *wound*, in a manner analogous to pain (cf. the theory of physical pain).[1] (A counterpart of this would be presented by mania, where the overflowing excitation is communicated to all associated neurons [Fig. 3].)[2] Here, then, there is a similarity to neurasthenia. In neurasthenia a quite similar impoverishment takes place owing to the excitation running out, as it were, through a hole. But in that case what is pumped empty is s. S. [somatic sexual excitation]; in melancholia the hole is in the

1 [This was discussed a little later by Freud in Sections 6 and 12 of Part I of the 'Project'. See, especially, p. 331 f. below, where references are also given to similar accounts in *Beyond the Pleasure Principle* (1920*g*), *RSE*, **18**, 29–30, and *Inhibitions, Symptoms and Anxiety* (1926*d*), ibid., **20**, 150–2. The analogy with 'an open wound' occurs in 'Mourning and Melancholia' (1916–17*g* [1915]), ibid., **14**, 226.]

2 [We have put this sentence in parentheses since otherwise it appears to interfere with the train of thought. What follows seems to be comparing neurasthenia not with mania but with melancholia.]



[Fig. 3]

psychical sphere. Neurasthenic impoverishment can, however, extend over to the psychical sexual group. And in fact the manifestations are so similar that some cases can be distinguished only with difficulty.

DRAFT H[1]
PARANOIA

In psychiatry *delusional* ideas [*Wahnvorstellung*] stand alongside of *obsessional* ideas [*Zwangsvorstellung*] as purely intellectual disorders,
[207] and paranoia stands alongside of obsessional insanity [*Zwangsirresein*] as an intellectual psychosis. If once obsessions have been traced back to an affective disturbance and proof has been found that they owe their strength to a conflict, then the same view must apply to delusions and they too must be the outcome of affective disturbances and must owe their strength to a psychological process. The contrary of this is

1 [Enclosed with a letter of January 24, 1895. – This is the first of Freud's many discussions of paranoia. A summary of the series is given in the Editors' Note to the Schreber analysis (*RSE*, **12**, 4–5). About a year later than the present draft he returned to the subject in a (less interesting) discussion in Draft K (p. 254 ff. below), which was later expanded into Section III of the second paper on the neuropsychoses of defence (1896*b*), *RSE*, **3**, 183 ff. Though the mechanism of projection is discussed here, there is no hint at all of the illness having a homosexual basis. That theory was first published by Freud in the Schreber analysis (1911*c*), ibid., **12**, 37 f. But he there tells us (ibid., 51) that 'during the last few years' he had been studying the question along with Jung and Ferenczi. Ernest Jones (1955, 303 and 281) mentions that Freud had raised the matter with Ferenczi on February 11, 1908 (he quotes part of this letter, ibid., 488), and with Jung a few days earlier, on January 27. In this last letter, Jones reports (ibid., 281), Freud said that 'he had learnt this from Fliess'. This was presumably by word of mouth, as there is no trace of it in the published Fliess papers. But in fact it seems likely that Freud had only taken up the idea seriously very shortly before these two letters to Jung and Ferenczi were written. A memorandum sent by Freud to Jung (see Freud, 1974*a*, 22 F, p. 38) has come to light, which deals in very considerable detail with the theory of paranoia but shows no hint of a homosexual basis. This memorandum is undated, but it was found in association with other letters to Jung dating from the first half of 1907, and William McGuire, editor of *The Freud/Jung Letters*, states in a footnote that it was written and posted between April 14 and 20, 1907.]

accepted by psychiatrists, while laymen are inclined to attribute delusional insanity to shattering mental events. 'A man who does not lose his reason over certain things can have no reason to lose.'[1]

Now it is in fact the case that paranoia in its classical form is a *pathological mode of defence*, like hysteria, obsessional neurosis and hallucinatory confusion. People become paranoic over things that they cannot put up with, provided that they possess the peculiar psychical disposition for it.

In what does this disposition consist? In a tendency to what represents the psychical characteristic of paranoia; and this we will consider in an example.

An unmarried woman, no longer very young (about thirty), shared a home with her brother and [elder] sister. She belonged to the upper working class; her brother was working himself up into becoming a small manufacturer. Meanwhile they let off a room to a fellow worker, a much-travelled, rather enigmatic man, very clever and intelligent. He lived with them for a year and was on the most companionable and sociable terms with them. After this he went away but returned after six months. This time he stopped for only a comparatively short time and then disappeared for good and all. The sisters used often to lament his absence and could speak nothing but good of him. Nevertheless, the younger sister told the elder one of an occasion when he made an attempt at getting her into trouble. She had been doing out the rooms while he was still in bed. He had called her up to the bed, and, when she unsuspectingly obeyed, put his penis in her hand. There had been no sequel to the scene, and [208]
soon afterwards the stranger had gone off.

In the course of the next few years the sister who had had this experience fell ill. She began to complain, and eventually developed unmistakable delusions of observation and persecution with the following content. She thought their women neighbours were pitying her for having been jilted and because she was still waiting for the man to come back: they were always making hints of that kind to her, kept on saying all kinds of things to her about the man, and so on. All this, she said, was of course untrue. Since then the patient has only fallen into this state for a few weeks at a time. Her insight then returns temporarily and she explains that it is all the result of getting excited; though even in the intervals she suffers from a neurosis which can easily be interpreted as a sexual one. And soon she falls into a fresh bout of paranoia.

1 [Lessing, *Emilia Galotti*, Act IV, Scene 7. The same quotation occurs in an unfinished paper of Freud's, 'Psychopathic Characters on the Stage' (1942*a* [1905–06]), *RSE*, **7**, 299.]

The elder sister was astonished to notice that, as soon as the conversation turned to the scene of the seduction, the patient used to repudiate it. Breuer heard of the case, the patient was sent to me and I endeavoured to cure her tendency to paranoia by trying to reinstate the memory of the scene. I failed in this. I talked to her twice, got her to tell me everything to do with the lodger in 'concentration' hypnosis.[1] In reply to my searching enquiries as to whether something 'embarrassing' had not happened all the same, I was met with the most decided negative, and – saw her no more. She sent me a message to say that it upset her too much. Defence! That was obvious. She *wished* not to be reminded of it and consequently intentionally repressed [*verdrängt*][T] it.[2]

Verdrängung

There could be no doubt whatever about the defence; but it might just as well have led to a hysterical symptom or an obsessional idea. What was the peculiarity of paranoic defence?

She was sparing herself something; something was repressed. We can guess what it was. She had probably really been excited by what she had seen and by its memory. So what she was sparing herself was the reproach of being a 'bad woman'. Afterwards she came to hear the same reproach from outside. Thus *the subject matter remained unaffected*; what was altered was something in the *placing* of the whole thing. Earlier it had been an internal self-reproach, now it was an imputation coming from outside. The judgement about her had been transposed outwards: people were saying what otherwise she would have said to herself. Something was gained by this. She would have had to accept the judgement pronounced from inside; she could reject the one arriving from outside. *In that way the judgement, the reproach, was kept away from her ego*.

[209]

The purpose of paranoia is thus to fend off an idea that is incompatible with the ego, by projecting its substance into the external world.[3]

Two questions arise: [1] How is a transposition of this kind brought about? [2] Does this apply also to other cases of paranoia?

(1) The transposition is effected very simply. It is a question of an abuse[4] of a psychical mechanism which is very commonly employed in

1 [A stage, soon abandoned by Freud, between hypnotic suggestion proper and free association. See p. 67 above.]

2 [For 'intentionally repressed', a phrase often used by Freud at this period, see a footnote to the 'Preliminary Communication' (1893*a*), *RSE*, **2**, 9.]

3 [The concept of projection (as well as the term) makes its first appearance in this passage. It was made public in the second paper on the neuropsychoses of defence (1896*b*), ibid., **3**, 191, but with much less detail than here.]

4 ['*Misbrauch*' in the MS., as at the end of the paragraph. Here only, *Anf*. mistakenly reads '*Ausbruch*' ('breaking out').]

normal life: transposition or projection. Whenever an internal change occurs, we have the choice of assuming either an internal or an external cause. If something deters us from the internal derivation, we shall naturally seize upon the external one. Secondly, we are accustomed to our internal states being betrayed (by an expression of emotion) to other people. This accounts for normal delusions of observation and normal projection. For they are normal so long as, in the process, we remain conscious of our own internal change. If we forget it and if we are left with only the leg of the syllogism that leads outwards, then there we have paranoia, with its overvaluation of what people know about us and of what people have done to us. What do people know about us that we know nothing about, that we cannot admit? *It is, therefore, abuse of the mechanism of projection for purposes of defence*.

Something quite analogous, indeed, takes place with obsessional ideas. The mechanism of substitution is also a normal one. When an old maid keeps a dog or an old bachelor collects snuff-boxes, the former is finding a substitute for her need for a companion in marriage and the latter for his need for – a multitude of conquests.[1] Every collector is a substitute for a Don Juan Tenorio, and so too is the mountaineer, the sportsman, and such people. These are erotic equivalents. Women know them too. Gynaecological treatment falls into this category. There are two kinds of [210]
women patients: one kind who are as loyal to their doctor as to their husband, and the other kind who change their doctors as often as their lovers. This normally operating mechanism of substitution is abused in obsessional ideas – once again for purposes of *defence*.

[2] And now, does this view apply also to other cases of paranoia? To all of them, I should have thought. But I will take some examples.

The litigious paranoic cannot put up with the idea that he has done wrong or that he should part with his property. He therefore thinks the judgement was not legally valid, that he is not in the wrong, etc. This case is too clear and perhaps not quite unambiguous; maybe it could be resolved more simply.

The '*grande nation*' cannot face the idea that it can be defeated in war. *Ergo* it was not defeated; the victory does not count. It provides an example of mass paranoia and invents the delusion of betrayal.[2]

1 [See also Freud (1895g), *RSE*, **2**, 297.]

2 [A reference to the aftermath of the Franco-Prussian War of 1870.]

The alcoholic will never admit to himself that he has become impotent through drink. However much alcohol he can tolerate, he cannot tolerate this insight. So his wife is to blame – delusions of jealousy and so on.

The hypochondriac will struggle for a long time before finding the key to his feelings of being seriously ill. He will not admit to himself that they arise from his sexual life; but it gives him the greatest satisfaction if his ailment is, as Moebius says, not endogenous but exogenous. So he is being poisoned.

The official who has been passed over for promotion requires that there should be a conspiracy against him and that he should be spied on in his room. Otherwise he would have to admit his shipwreck.

What develops like this need not always be delusions of persecution. Megalomania may perhaps be even more effective in keeping the distressing idea away from the ego. Take, for instance, a cook who has lost her looks, and who must accustom herself to the thought that she is permanently excluded from happiness in love. This is the right moment for the emergence of the gentleman from the house opposite, who clearly wants to marry her and who is giving her to understand as much in such a remarkably bashful but nonetheless unmistakable fashion.

In every instance the *delusional idea* is maintained with the same
[212] energy with which another, intolerably distressing, idea is fended off from the ego. Thus they love *their delusions as they love themselves*. That is the secret.

And now, how does this form of defence compare with those that we already know: (1) hysteria, (2) obsessional idea, (3) hallucinatory confusion, (4) paranoia? We have to take into account: affect, content of the idea and hallucinations. [Cf. Fig. 4.]

(1) *Hysteria*. The incompatible idea is not admitted to *association* with the ego. The content is retained in a segregated compartment, it is absent from consciousness; its affect [is got rid of][1] by conversion into the somatic sphere. – Psychoneurosis is the only [result].[2]

(2) *Obsessional idea*. Once more, the incompatible idea is not admitted to *association*. The affect is retained; the content is replaced by a substitute.

(3) *Hallucinatory confusion*. The whole incompatible idea – affect and content – is kept away from the ego; and this is only possible at the

1 [The verb is missing in the MS. *Anf*., 124, supplies, not very convincingly, '*verschoben*' ('displaced'). 'Got rid of' ('*erledigt*') is derived from Freud's own tabular summary (Fig. 4).]

2 [The MS. has '*Psychoneurose die einzige*'. These rather obscure words are omitted in *Anf*., 124. The editors of the later (1986) German edition point out that '*die einzige*' was apparently added as an afterthought.]

SUMMARY

fended off

	Affect	Content of idea	Hallucination	Outcome
Hysteria	got rid of by conversion –	– absent from consciousness	–	Unstable defence with satisfactory gain
Obsessional Idea	retained +	– absent from consciousness substitute found	–	Permanent defence without gain
Hallucinatory Confusion	absent –	– absent	friendly to ego friendly to defence	Permanent defence brilliant gain
Paranoia	retained +	+ retained projected out	hostile to ego friendly to defence	Permanent defence without gain
Hysterical Psychosis	dominates +	consciousness +	hostile to ego hostile to defence	Failure of defence

[Fig. 4]

price of a partial detachment from the external world. Recourse is had to hallucinations, which are *friendly to the ego and support the defence*.

(4) *Paranoia*. The content and affect of the incompatible idea are retained, in direct contrast to (3); but they are projected into the external world. Hallucinations, which arise in some forms of the illness, are *hostile to the ego* but support the defence.

[5] In hysterical psychoses, on the contrary, it is precisely the ideas fended off that gain the mastery. The type of these is the attack and the *état secondaire*. The hallucinations are *hostile to the ego*.

The *delusional idea* is either a copy of the idea fended off or its contrary (megalomania). Paranoia and hallucinatory confusion are the two *psychoses of defiance or contrariness*. The 'reference to oneself' in paranoia is analogous to the hallucinations in confusional states, for these seek to assert the exact contrary of the fact that has been fended off. Thus the reference to oneself always seeks to prove the correctness of the projection.

LETTER 22[1]

[213] . . . I have nothing to report to you. At most a small analogy to Emma's dream psychosis that we witnessed.[2] Rudi Kaufmann, a very intelligent nephew of Breuer's, and a medical student too, is a late riser. He gets himself called by a servant, but is very reluctant about obeying her. One morning she woke him up a second time and, as he would not respond, called him by his name: 'Herr Rudi!' Thereupon the sleeper had a hallucination of a noticeboard over a hospital bed (cf. the Rudolfinerhaus)[3] with the name 'Rudolf Kaufmann' on it, and said to himself: 'R. K.'s in hospital in any case, then; so I needn't go there!' and went on sleeping.[4]

. . . . . .

1 [Dated Vienna, March 4, 1895.]

2 [Emma reappears in the 'Project' (p. 378 f. below). She figures prominently in other parts of the correspondence, not included here. Fliess operated on her nose, with unhappy consequences. The German editors of the 1985 edition of these letters present good evidence to suggest that she appears again in *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 112, as the patient who underwent an unsuccessful 'jaw' operation followed by a dream of convenience very similar to the analogous one reported here. She is believed also to be the patient 'Irma' in Freud's (1900*a*) famous specimen dream (see Schur, 1966*a*).]

3 [A private hospital in Vienna. – 'Rudi' is the familiar short form of 'Rudolf'.]

4 [This, perhaps the earliest recorded wishful 'dream of convenience', was introduced by Freud into *The Interpretation of Dreams*, ibid., **4**, 111 f. and 207. He used it again in his last, posthumous, work, *An Outline of Psychoanalysis* (1940*a*), ibid., **23**, 153.]

DRAFT I[1]
MIGRAINE: ESTABLISHED POINTS

(1) *A matter of summation*. There is an interval of hours or days between the trigger and the outbreak of the symptoms. One has a sort of feeling that an obstacle is being overcome and that a process then goes forward.

(2) *A matter of summation*. Even without a trigger one has an impression that there must be an accumulating stimulus which is present in the smallest quantity at the beginning of the interval and in the largest quantity towards its end.

(3) *A matter of summation*, in which susceptibility to aetiological factors lies in the height of the level of the stimulus already present.

(4) A matter with a *complicated aetiology*. Perhaps on the pattern of a [214]
chain aetiology, where a proximate cause can be produced by a number of factors[2] directly and indirectly, or on the pattern of a surrogate[3] aetiology, where, alongside of a specific cause, stock causes can act as quantitative substitutes.[4]

(5) A matter on the model of menstrual migraine and belonging to the sexual group. Evidence:

(*a*) Rarest in healthy males.

(*b*) Restricted to the sexual time of life: childhood and old age almost excluded.

(*c*) If it is produced by summation, sexual stimulus too is something produced by summation.

(*d*) The analogy of periodicity.

(*e*) Frequency in people with disturbed sexual discharge (neurasthenia, *coitus interruptus*).

1 [This MS. is undated. It does not form part of the rest of the collection of 'Fliess Papers', but was in the possession of Dr Robert Fliess in New York. It initially appeared to be a document referred to as having been recently written, in a portion, not published here, of Letter 22 above. This is dated March 4, 1895. That, however, has subsequently turned out to be something else Freud was writing at the time (Freud, 1895*j*), *NSW*, **4**. It seems most likely that it was written in the autumn of 1895, when migraine was a frequent topic of discussion between Freud and Fliess. The editors of the 1986 German edition consider it best placed with a letter dated November 8, 1895, not reprinted here. – Both Freud and Fliess were sufferers from migraine and it was a major focus of interest to Fliess. See Jones, 1953, 339, and *The Psychopathology of Everyday Life* (1901*b*), *RSE*, **6**, 19.]

2 ['*Durch viele Momente*' in the MS. *Anf*., 126, reads '*Monate*' ('over a number of months').]

3 [Misread as 'summation' in *Anf*. and therefore *SE*.]

4 [For the various kinds of aetiological factors, see Freud's probably contemporary second paper on anxiety neurosis (1895*f*), *RSE*, **3**, 120 ff. There is a mention of migraine in that same paper (ibid., 118) and summation is also discussed (ibid., 115).]

(6) Certainty that migraine can be produced by chemical stimuli: human toxic emanations,[1] sirocco,[2] fatigue, smells. Now, sexual stimulus, too, is a chemical one.[3]

(7) Cessation of migraine during pregnancy, when production is probably directed elsewhere.

This would seem to show that migraine is a toxic effect produced by the sexual stimulating substance[4] when this cannot find sufficient discharge. And perhaps one should add to this that there is a particular path present (whose location has to be determined) which is in a state of special susceptibility. The question about this is the question of the localization of migraine.

(8) In regard to this path we have indications that organic diseases of the cranium, tumours and suppurations (without toxic intermediate links?) produce migraine or something similar, further that migraine is *unilateral*, is connected with the nose and is linked with localized paralytic phenomena. The first of these signs is not unambiguous. The unilaterality, localization over the eye and complication by localized paralyses are more important.

(9) The painfulness of migraine can only suggest the cerebral
[215] meninges, since affections of the cerebral *substance* are certainly painless.

(10) If in this way migraine seems to approach neuralgia, this tallies with summation, sensitivity and its oscillations, the production of neuralgias through toxic stimuli. *Toxic neuralgia* will thus be its physiological prototype. The scalp is the seat of its pain and the trigeminal is its pathway. Since, however, the neuralgic change can only be a central one, we must suppose that the topical[5] centre for migraine is a trigeminal nucleus whose fibres supply the dura mater.

Since the pain in migraine is similarly located to that in supraorbital neuralgia, this dural nucleus must be in the neighbourhood of the nucleus of the first division. Since the different branches and nuclei of the trigeminal influence one another, all other affections of the trigeminal can contribute to the aetiology [of migraine] as concurrent (not as stock) factors.

1 [Further mentioned below, p. 416.]

2 [Cf. Letter 14, p. 213 above.]

3 [See p. 215 *n.* 5 above.]

4 [See Draft D, p. 215 above.]

5 [Misread as 'logical' in *Anf.* and *SE.*]

The symptomatology and biological position of migraine

The pain of a neuralgia usually finds its discharge in tonic tension (or even in clonic spasms). Therefore it is not impossible that migraine may include a spastic innervation of the muscles of blood vessels in the reflex sphere of the dural region. We may ascribe to this intervention the general (and, indeed, the local) disturbance of function which does not differ symptomatically from a similar disturbance due to vascular constriction. (Cf. the similarity of migraine to attacks of thrombosis.) Part of the inhibition is due to the pain in itself. It is presumably the vascular area of the choroid plexus which is first affected by the spasm of discharge. The relation to the eye and nose is explained by their common innervation by the first division [of the trigeminal].[1]

DRAFT J[2]
FRAU P. J. (AGED 27)

[1]

She had been married for three months. Her husband, a commercial traveller, had had to leave her a few weeks after their marriage and had already been away for weeks on end. She missed him very much and longed for him. She had been a singer, or at any rate had been trained as one. To pass the time, she was sitting at the piano singing, when suddenly she felt ill – in her abdomen and stomach, her head swam, she had feelings of oppression and anxiety and cardiac paraesthesia; she thought she was going mad. A moment later it occurred to her that she had eaten eggs and mushrooms that morning, and she concluded that she had been poisoned. However, the condition quickly passed off. Next day the maidservant told her that a woman living in the same house had gone mad. From that time on she was never free of an obsession [*Zwangsidee*], accompanied by anxiety, that she was going to go mad too. [216]

1 [Freud returned to the subject of migraine in the later part of Letter 39 of January 1, 1896, printed here as Appendix B to the 'Project', on p. 413 below. See also Freud (1895*f*), *NSW*, **4**; *RSE*, **3**, 137 ff.]

2 [Undated. There seems to be no precise evidence. The editors of *Anf.* assign it to the end of 1895 on the basis of the handwriting and a possible resemblance in the 'form' of the case history to that of the Emma case reported in the 'Project' (p. 378 f. below) – presumably the fact of there being a 'Scene I' and a 'Scene II' in both. The reference at several points to the 'pressure technique' suggests that the date may in fact be earlier than this. (See p. 67 above.)]

Such is the outline of the case. I assumed to start with that her condition then had been an anxiety attack – a release of sexual feeling which was transformed into anxiety. An attack of that kind, I was afraid, might take place without any accompanying psychical process. Nevertheless, I would not reject the more favourable possibility that such a process might be found; on the contrary, I would take it as the starting point of my work. What I expected to find was this. She had had a longing for her husband – that is, for sexual relations with him; she had thus come upon an idea which had excited sexual affect and afterwards defence against the idea; she had then taken fright and made a false connection or substitution.[1]

I began by asking her about the subsidiary circumstances of the event: something must have reminded her of her husband. She had been singing Carmen's aria 'Près des remparts de Séville'.[2] I asked her to repeat it for me; she could not even recall the words exactly. – At what point do you think the attack came on? – She did not know. – When I applied pressure [to her forehead],[3] she said it had been *after* she had finished the aria. That seemed quite possible: it had been a train of thought brought up by
[217] the text of the aria. – I then asserted that before the attack there had been thoughts present in her which she might not remember. In fact she remembered nothing, but pressure [on her forehead] produced 'husband' and 'longing'. The latter was further specified, on my insistence, as longing for sexual caresses. – 'I'm quite ready to believe that. After all, your attack was only a state of outpouring of love. Do you know the page's song?

> Voi che sapete che cosa è amor,
> Donne vedete s'io l'ho nel cor. . . .[4]

There was certainly something besides this: a feeling in the lower part of the body, a cramp and an urgent need to urinate.' – She now confirmed this. The insincerity of women starts from their omitting the characteristic sexual symptoms in describing their states. So it had really been an *orgasm*.

'Well you can see, anyhow, that a state of longing like that in a young woman who has been left by her husband cannot be anything to be

1 [For 'false connection' see Section II of the first paper on the neuropsychoses of defence (1894*a*), *RSE*, **3**, 49 *n*. 2.]

2 [The *seguidilla* from Act I of Bizet's opera.]

3 [See footnote 2, p. 243 above.]

4 [Cherubino's *canzonetta* from Act II of Mozart's *Figaro*.]

ashamed of.' – On the contrary, she thought, that is how it should be.[1] – 'Very well; but in that case I can see no reason for fright. You were certainly not frightened about "husband" and "longing"; so there must be some other thoughts missing, which are more appropriate to the fright.' – But she only added that she had all along been afraid of the pains that intercourse caused her, but that her longing had been much stronger than her fear of the pains. – At this point we broke off.

II

It was much to be suspected that in Scene I (by the piano), alongside of her longing thoughts for her husband (which she remembered), she had entered on another, deep-going train of thought, which she did *not* remember and which led to a Scene II. But I still did not as yet know its starting point. Today she arrived weeping and in despair, evidently without any hope of the treatment succeeding. So her resistance was already stirred up and progress was far more difficult. What I wanted to know, then, was what thoughts that might lead to her being frightened were still present. She brought up all kinds of things that could not be relevant: the fact that for a long time she had not been deflowered (which Professor Chrobak[2] had confirmed to her), that she attributed her nervous state to that and for that reason wished it might be done. – This was, of course, a thought from a later time: till Scene I she had been in good health. – At last I obtained the information that she had already had a similar, but [218]
much weaker and more transitory, attack with the same feelings. (From this I saw that it was from the mnemic picture of the orgasm itself that the path leading down to the deeper layers took its start.) We investigated the other scene. At that time – four years back – she had had an engagement at Ratisbon. In the morning she had sung at a rehearsal and had given satisfaction. In the afternoon, at home, she had had a 'vision' – as if there were something, a 'row', between her and the tenor of the company and another man, and afterwards she had had the attack, with the fear that she was going mad.

Here then was a Scene II, which had been touched on by association in Scene I. But it was evident that here, too, the memory had gaps in it. There must have been other ideas present in order to account for the release of sexual feeling and the fright. I asked for these intermediate links, but instead I was told her motives [*Motive*][T]. She had disliked the

1 ['*was so sein soll*' ('as it should be'); misread in *SE* as 'something to be approved of'.]

2 [Professor of Gynaecology at Vienna, 1880–1908.]

whole of life on the stage. – 'Why?' – The brusqueness of the manager and the actors' relations to one another. – I asked for details of this. – There had been an old comic actress with whom the young men used to joke by asking her if they might come and spend the night with her. – 'Something further, about the tenor.' – He had pestered her, too; at the rehearsal he had put his hand on her breast. – 'Through your clothes or on the bare skin?' – At first she said the latter, but then took it back: she had been in outdoor clothes. – 'Well, what more?' – The whole character of their relations, all the hugging and kissing among the players had been frightful to her. – 'Yes?' – Once again the manager's brusqueness, and she had only stayed there a few days. – 'Was the tenor's assault made on the same day as your attack?' – No; she did not know if it had been earlier or later. – My enquiries with the help of pressure showed that the assault had been on the fourth day of her stay and her attack on the sixth.

Interrupted by the patient's flight.

NOTE

During the whole of the later part of the year 1895 Freud was largely occupied with the fundamental theoretical problem of the relation between his emerging psychology and established neurology. His reflections finally led to the uncompleted work which we have named a 'Project for a Scientific Psychology'. This draft was written in September and October, 1895, and should appear, chronologically, at this point in the Fliess papers. It stands so much apart, however, from the rest of them, and constitutes such a formidable and self-contained entity, that it has seemed advisable to print it in a detached shape at the end of this volume. One letter, No. 39, written on January 1, 1896, is so closely connected with the 'Project' (apart from which, indeed, it would be unintelligible) that it too has been removed from its proper place in the correspondence and printed as an Appendix to the 'Project'. That Freud had also during all this period been concerned with clinical matters as well is conclusively shown by the fact that on the very same day on which he despatched this letter (January 1, 1896) he also sent Fliess Draft K, which follows here and is in many respects a full preliminary sketch of his second paper on the neuropsychoses of defence (1896*b*), completed very soon afterwards. [219]

DRAFT K[1]
THE NEUROSES OF DEFENCE

(*A Christmas Fairy Tale*)

[220] There are four types of these and many forms. I can only make a comparison between hysteria, obsessional neurosis and one form of paranoia. They have various things in common. They are pathological aberrations of normal psychical affective states: of *conflict* (hysteria), of *self-reproach*[2] (obsessional neurosis), of *mortification* (paranoia), of *mourning* (acute hallucinatory amentia). They differ from these affects in that they do not lead to anything being settled but to permanent damage to the ego. They come about subject to the same precipitating causes as their affective prototypes, provided that the cause fulfils two more preconditions – that it is of a sexual kind and that it occurs during the period before sexual maturity (the preconditions of sexuality and *infantilism*). About preconditions applying to the individual concerned I have no fresh knowledge. In general I should say that heredity is a further precondition, in that it facilitates and increases the pathological affect – the precondition, that is, which mainly makes possible the gradations between the normal and the extreme case. I do not believe that
[221] heredity determines the choice of the particular defensive neurosis.

There is a normal trend towards defence – that is, an aversion to directing psychical energy in such a way that unpleasure [*Unlust*][T] results. This trend, which is linked to the most fundamental conditions of the psychical mechanism (the principle of constancy), cannot be employed against perceptions, for these are able to compel attention (as is evidenced by their consciousness); it only comes in question against memories and

1 [This was enclosed in Letter 39, of January 1, 1896, which is mentioned on the previous page and can be found on p. 413 below. It was therefore no doubt written during the preceding days: hence its subtitle. This is in some parts a fairly close precursor to the second paper on the neuropsychoses of defence (1896*b*), which was sent off by Freud to the publishers scarcely more than a month after this (on February 5). – Freud was beginning at this time to be engaged in the problem of the differential aetiology of the neuroses – the 'choice of neurosis', as he called it – which was to remain unsolved for many years. The present draft and Letters 46 and 52 are largely concerned with it, as are the contemporary published papers 1896*a*, 1896*b* and 1896*c*. A detailed account of his successive attempts at a solution is given in the Editors' Note to 'The Disposition to Obsessional Neurosis' (1913*i*), *RSE*, **12**, 309 ff. The final explanation had to await the investigation of the developmental stages of the libido and the concepts of fixation and regression. These later ideas are made plain in Lectures XXI and XXII of the *Introductory Lectures* (1916–17*a*), ibid., **16**, 282 ff. and 299 ff.]

2 [Simply '*Vorwurf*' ('reproach') in the original. Both here and in his published writings this was Freud's habitual usage. Only very occasionally, and with no apparent change in meaning, he writes '*Selbstvorwurf*' ('self-reproach') – e.g. on p. 260 below.]

thoughts. It is innocuous where it is a matter of ideas to which unpleasure was at one time attached but which are unable to acquire any contemporary unpleasure (other than remembered unpleasure), and in such cases too it can be overridden by psychical interest.

The trend towards defence becomes detrimental, however, if it is directed against ideas which are also able, in the form of memories,[1] to release fresh unpleasure – as is the case with sexual ideas. Here, indeed, the one possibility is realized of a memory having a greater releasing power subsequently [*nachträglich*][T] than had been produced by the experience corresponding to it.[2] Only one thing is necessary for this: that puberty should be interpolated between the experience and its repetition in memory – an event which so greatly increases the effect of the revival. The psychical mechanism seems unprepared for this exception, and it is for that reason a necessary precondition of freedom from neuroses of defence that no considerable sexual irritation should occur before puberty, though it is true that the effect of such an experience must be increased by hereditary disposition before it can reach a pitch capable of causing illness.

(Here a subsidiary problem branches off: how does it come about that under analogous conditions, perversion or simple immorality emerges instead of neurosis?)[3]

We shall be plunged deep into psychological riddles if we enquire into the origin of the unpleasure which seems to be released by premature sexual stimulation and without which, after all, a repression cannot be explained. The most plausible answer will appeal to the fact that shame and morality are the repressing forces and that the neighbourhood in which the sexual organs are naturally placed must inevitably arouse disgust during sexual experiences.[4] Where there is no shame (as in a male [222]
person), or where no morality comes about (as in the lower classes of society), or where disgust is blunted by the conditions of life (as in the country), there too no repression and therefore no neurosis will result from sexual stimulation in infancy. I fear, nevertheless, that this explanation will not stand up to deeper testing. I do not think that the release of unpleasure during sexual experiences is the consequence

1 ['*Erinner*[*un*]*gen*', in the MS. *Anf.*, 157, has '*Energie*' ('energy').]

2 [This is the hypothesis of *Nachträglichkeit* (deferred action). See the comment in the Editors' footnote on the similar passage near the end of Section 4 of Part II of the 'Project' (p. 380 *n.* 3 below).]

3 [This seems to be the first mention of the relation between perversion and neurosis. See p. 265 below.]

4 [Cf. the 'Dora' case history (1905*e*), *RSE*, **7**, 29, where further references are given.]

of the chance admixture of certain unpleasurable factors. Everyday experience teaches us that if libido reaches a sufficient height disgust is not felt and morality is overridden; and I believe that the generation of shame is connected with sexual experience by deeper links. In my opinion there must be an independent source for the release of unpleasure in sexual life: once that source is present, it can activate sensations of disgust, lend force to morality, and so on. I hold to the model of anxiety neurosis in adults, where a quantity deriving from sexual life similarly causes a disturbance in the psychical sphere, though it would ordinarily have found another use in the sexual process. So long as there is no correct theory of the sexual process, the question of the origin of the unpleasure operating in repression remains unanswered. [See footnote 1, p. 297 below.]

The course taken by the illness in neuroses of repression is in general always the same: (1) The sexual experience (or series of experiences) which is traumatic and premature and is to be repressed. (2) Its repression on some later occasion which arouses a memory of it; at the same time the formation of a primary symptom. (3) A stage of successful defence, which is equivalent to health except for the existence of the primary symptom. (4) The stage in which the repressed ideas return, and in which, during the struggle between them and the ego, new symptoms are formed which are those of the illness proper. (5)[1] A stage of adjustment, of being overwhelmed, or of recovery with a malformation.[2]

[223] The main differences between the various neuroses are shown in the way in which the repressed ideas return; others are seen in the manner in which the symptoms are formed and in the course taken by the illness. But the specific character of a particular neurosis lies in the fashion in which the repression is accomplished.

1 [The (5) was overlooked in *Anf.* and *SE*, with the result that this stage was conflated with stage (4).]

2 [Here, for the first time, is what might be called the standard formula for the development of a neurosis. It is repeated, in a less schematic shape, in the second paper on the neuropsychoses of defence (1896*b*), *RSE*, **3**, 179 f. But it is implied in discussions of neurosis throughout Freud's writings, even in quite late ones. The fact, for instance, that stage (4), the return of the repressed, constitutes the illness proper is insisted on in the paper 'The Loss of Reality in Neurosis and Psychosis' (1924*e*), ibid., **19**, 179; the possibility of an 'overwhelming' of the ego – mentioned below (pp. 252 and 254–5), in the first paper on the neuropsychoses of defence (1894*a*), *RSE*, **3**, 51 f., and in *Studies on Hysteria* (1895*d*), ibid., **2**, 234–5 – is often considered later – e.g. in *The Ego and the Id* (1923*b*), ibid., **19**, 51, and in *Moses and Monotheism* (1939*a*), ibid., **23**, 72; while the possibility of a malformation (or alteration) of the ego resulting (mentioned below, p. 254, and in the second paper on the neuropsychoses of defence, 1896*b*; *RSE*, **3**, 192 f.) is particularly emphasized in 'Analysis Terminable and Interminable' (1937*c*), ibid., **23**, 211 ff. The compromise character of symptoms, also suggested here, though more explicitly stated at several later points in this draft (e.g. pp. 251–2 and 254 below), was insisted upon to the last. See for instance *Moses and Monotheism* (1939*a*), *RSE*, **23**, 70.]

The course of events in obsessional neurosis is what is clearest to me, because I have come to know it the best.

OBSESSIONAL NEUROSIS

Here the primary experience has been accompanied by pleasure [*Lust*]. Whether an active one (in boys) or a passive one (in girls), it was without pain or any admixture of disgust; and this in the case of girls implies a comparatively high age in general (about eight years). When this experience is remembered later, it gives rise to a release of unpleasure; and, in particular, there first emerges a self-reproach, which is conscious. It seems, indeed, as though the whole psychical complex – memory and self-reproach – is conscious to start with. Later, both of them, without anything fresh supervening, are repressed and in their place an *antithetic symptom*, some nuance of *conscientiousness*, is formed in consciousness.

The repression may come about owing to the memory of the pleasure itself releasing unpleasure when it is reproduced in later years; this should be explicable by a theory of sexuality. But things may happen differently as well. In *all* my cases of obsessional neurosis, at a very early age, years before the experience of pleasure, there had been a *purely passive* experience; and this can hardly be accidental.[1] If so, we may suppose that it is the later convergence of this passive experience with the experience of pleasure that adds the unpleasure to the pleasurable memory and makes repression possible. So that it would be a necessary clinical precondition of obsessional neurosis that the passive experience should happen early enough not to be able to prevent the spontaneous occurrence of the experience of pleasure. The formula would therefore run: [224]

Unpleasure – Pleasure – Repression.

The determining factor would be the chronological relations of the two experiences to each other and to the date of sexual maturity.

At the stage of the return of the repressed,[2] it turns out that the *self-reproach* returns unaltered, but rarely in such a way as to draw attention to itself; for a while, therefore, it emerges as a pure sense of guilt

1 [This is emphasized in the second paper on the neuropsychoses of defence, where some later references to the point are mentioned in an Editors' footnote (*RSE*, **3**, 178 *n.* 2). The distinction between a passive aetiology for hysteria and an active one for obsessional neurosis, held by Freud at this time, was given up by him soon afterwards (see Letter 46, p. 256 ff. below).]

2 ['*Wiederkehr des Verdrängten*.' The first actual occurrence of the phrase: its first published appearance was in the second paper on the neuropsychoses of defence (1896*b*), *RSE*, **3**, 179.]

without any content. It usually becomes linked with a content which is distorted in two ways – in time and in content: the former insofar as it relates to a contemporary or future action, and the latter insofar as it signifies not the real event but a surrogate chosen from the category of what is analogous – a substitution. An obsessional idea is accordingly a product of compromise, correct as regards affect and category but false owing to chronological displacement [*Verschiebung*] and substitution by analogy.

The affect of the self-reproach may be transformed by various psychical processes into other affects, which then enter consciousness more clearly than the affect itself: for instance, into *anxiety* (fear of the consequences of the action to which the self-reproach applies), *hypochondria* (fear of its bodily effects), *delusions of persecution* (fear of its social effects), *shame* (fear of other people knowing about the objectionable action), and so on.

The conscious ego regards the obsession as something alien to itself: it withholds belief from it, by the help, it seems, of the antithetic idea of conscientiousness, formed long before. But at this stage it may at times happen that the ego is overwhelmed by the obsession – for instance, if the ego is affected by an episodic melancholia. Apart from this, the stage of illness is occupied by the defensive struggle of the ego against the
[225] obsession; and this may itself produce new symptoms – those of the *secondary defence*. The obsessional idea, like any other, is attacked by logic, though its compulsive force is unshakeable. The secondary symptoms are an intensification of conscientiousness, and a compulsion to examine things and to hoard them. Other secondary symptoms arise
Übertragung if the compulsion is transferred [*überträgt*][T] to motor impulses against the obsession – for instance, to brooding, drinking (*dipsomania*), protective ceremonials, *folie du doute*.

Here, then, we arrive at the formation of three kinds of symptoms:

(*a*) the primary symptom of defence – *conscientiousness*,

(*b*) the compromise symptoms of the illness – *obsessional ideas or obsessional affects*,

(*c*) the secondary symptoms of defence – *obsessional brooding, obsessional hoarding, dipsomania, obsessional ceremonials.*

Those cases in which the content of the memory has not become admissible to consciousness through substitution, but in which the affect of self-reproach has become admissible through transformation, give one the impression of a displacement having occurred along a chain of inferences: I reproach myself on account of an event – I am afraid other people

know about it – therefore I feel ashamed in front of other people. As soon as the first link in this chain is repressed, the obsession jumps on to the second or third link, and leads to two forms of delusions of observation, which, however, are in fact part of the obsessional neurosis. The defensive struggle terminates in general doubting-mania or in the development of the life of an eccentric with an indefinite number of secondary defensive symptoms – that is, if such a termination is reached at all.

It further remains an open question whether the repressed ideas return of their own accord, without the assistance of any contemporary psychical force [*Kraft*][T], or whether they need this kind of assistance at every fresh wave of their return. My experiences indicate the latter alternative. States of contemporary unsatisfied libido, it seems, are what employ the force of their unpleasure to arouse the repressed self-reproach. Once this arousal has occurred and symptoms have arisen through the impact of the repressed on the ego, then, no doubt the repressed ideational material[1] continues to operate on its own account; but in the oscillations of its quantitative power it always remains dependent on the quota of libidinal tension present at the moment. Sexual tension which, owing to being satisfied, has no time to turn into unpleasure remains harmless. Obsessional neurotics are people who are subject [226]
to the danger that eventually the whole of the sexual tension generated in them daily may turn into self-reproach or rather into the symptoms resulting from it, although at the present time they would not recognize the primary self-reproach afresh.

Obsessional neurosis can be cured if we undo all the substitutions and affective transformations that have taken place, till the primary self-reproach and the experience belonging to it can be laid bare and placed before the conscious ego for judging anew. In doing this we have to work through an incredible number of intermediate or compromise ideas which become obsessional ideas temporarily. We gain the liveliest conviction that it is impossible for the ego to direct on to the repressed material the part of the psychical energy to which conscious thought is linked. The repressed ideas – so we must believe – are present in and enter without inhibition into the most rational trains of thought; and the memory of them is aroused too by the merest allusions. The suspicion that 'morality' is put forward as the repressing force only as a pretext is confirmed by the experience that resistance during the therapeutic work avails itself of every possible motive of defence.

1 ['*Vorstellungsmasse*' in the MS. In *Anf.*, 162, '*Vorstellungs*' is omitted.]

PARANOIA[1]

The clinical determinants and chronological relations of pleasure and unpleasure in the primary experience are still unknown to me. What I have distinguished is the fact of repression, the primary symptom and the stage of illness as determined by the return of the repressed ideas.

The primary experience seems to be of a similar nature to that in obsessional neurosis; repression occurs after the memory of it has released unpleasure – it is unknown how. No self-reproach, however, is formed and afterwards repressed; but the unpleasure generated is referred to the patient's fellow men in accordance with the psychical formula of projection. The primary symptom formed is *distrust* (sensitiveness to other people). In this, belief has been withheld from a self-reproach.

We may suspect the existence of different forms, according to whether only the affect is repressed by projection or the content of the experience too, along with it. So, again, what returns may be merely the distressing affect or the memory as well. In the second case, which is the only one I am closely acquainted with, the content of the experience returns as a
[227] thought that occurs to the patient or as a visual or sensory hallucination. The repressed affect seems invariably to return in hallucinations of voices.

The returning portions of the memory are distorted by being replaced by analogous images from the present day – that is, they are simply distorted by a chronological replacement and not by the formation of a surrogate.[2] The voices, too, bring back the self-reproach as a compromise symptom and they do so, firstly, distorted in its wording to the pitch of being indefinite and changed into a threat; and, secondly, related not to the primary experience but precisely to the distrust – that is, to the primary symptom.

Since belief has been withheld from the primary self-reproach, it is at the unrestricted command of the compromise symptoms. The ego does not regard them as alien to itself but is incited by them to make attempts at explaining them which may be described as *assimilatory delusions*.[3]

At this point, with the return of the repressed in distorted form, the defence has at once failed; and the assimilatory delusions cannot be interpreted as a symptom of secondary defence but as the beginning of an *alteration of the ego*, an expression of its having been overwhelmed.[4]

1 [Cf. Draft H, p. 234 above.]

2 [Cf. pp. 251–2 above.]

3 [In the second paper on the neuropsychoses of defence (1896*b*), *RSE*, **3**, 192 f., these are spoken of as 'combinatory' or 'interpretative' delusions. Cf. pp. 270–1 below.]

4 [See footnote 2, p. 250 above.]

The process reaches its conclusion either in melancholia (a sense of the ego's littleness), which, in a secondary manner, attaches to the distortions the belief which has been withheld from the primary self-reproach,[1] or – what is more frequent and more serious – in *protective delusions* (megalomania), till the ego has been completely remodelled.

The determining element of paranoia is the mechanism of projection involving the refusal of belief in the self-reproach. Hence the common characteristic features of the neurosis: the significance of the voices as the means by which other people affect us, and also of gestures, which reveal other people's mental life to us; and the importance of the *tone* of remarks and *allusions* in them – since a direct reference from the *content* of remarks to the repressed memory is inadmissible to consciousness.

In paranoia repression takes place after a complicated conscious process of thought (the withholding of belief). This may perhaps be an [228] indication that it first sets in at a later age than in obsessional neurosis and hysteria. The preconditions of repression are no doubt the same. It remains a completely open question whether the mechanism of projection is entirely a matter of individual disposition or whether it is selected by particular temporal and accidental factors.

Four kinds of symptoms:

(*a*) primary symptoms of defence,
(*b*) compromise symptoms[2] of the return,
(*c*) secondary symptoms of defence,
(*d*) symptoms of the overwhelming of the ego.

HYSTERIA

Hysteria necessarily presupposes a primary experience of unpleasure – that is, of a passive nature. The natural sexual passivity of women explains their being more inclined to hysteria. Where I have found hysteria in men, I have been able to prove the presence of abundant sexual passivity in their anamneses. A further condition of hysteria is that the primary experience of unpleasure shall not occur at too early a time, at which the release of unpleasure is still too slight and at which, of course, pleasurable events may still follow independently. Otherwise what will follow will be only the formation of obsessions. For this reason we often find in men a combination of the two neuroses or the replacement of an initial hysteria by a later obsessional neurosis. Hysteria begins with the overwhelming of the ego, which is what paranoia leads to. The raising of tension at the

1 ['*Primärvorwurf*' in the MS. *Anf*., 164, has '*Primärvorgang*' ('primary process').]

2 ['*Kompromiss Symptome*' in the MS. *Anf*., 164, has '*Kompromisscharakter*' ('compromise nature').]

primary experience of unpleasure is so great that the ego does not resist it and forms no psychical symptom but is obliged to allow a manifestation
abführen of discharge [*Abfuhräusserung*]^{T} – usually an excessive expression of excitation [*Erregung*]^{T}. This first stage of hysteria may be described as 'fright hysteria'; its primary symptom is the *manifestation of fright* accompanied by a *gap* in the psyche. It is still unknown up to how late an age this first hysterical overwhelming of the ego can occur.

Repression and the formation of defensive symptoms only occur subsequently [*nachträglich*], in connection with the memory; and thenceforward *defence* and *overwhelming* (that is, the formation of symptoms and the outbreak of attacks) may be combined to any extent in hysteria.

Repression does not take place by the construction of an excessively
[229] strong antithetic idea [p. 149 above] but by the intensification of a boundary idea, which thereafter represents the repressed memory in the passage of thought. It may be called a *boundary idea* because on the one hand it belongs to the ego and on the other hand forms an undistorted portion of the traumatic memory. So, once again, it is the result of a compromise; this, however, is not manifested in a replacement on the basis of some category of subject matter, but by a displacement of attention along a series of ideas linked by temporal simultaneity. If the traumatic event found an outlet for itself in a motor manifestation, it will be this that becomes the boundary idea and the first symbol of the repressed material. There is thus no need to assume that some idea is being suppressed at each repetition of the primary attack; it is a question in the first instance of a *gap in the psyche*.

LETTER 46[1]

. . . As the fruit of some tormenting reflections, I send you the following solution to the aetiology of the psychoneuroses, which still awaits confirmation from individual analyses. Four periods of life are to be distinguished [Fig. 5]:

Ages

I*a*	I*b*	A	II	B	III
up to 4 years	up to 8		up to 14		up to *x*
Preconscious[2]	Infantile		Prepubertal		Maturity

[Fig. 5]

1 [Dated Vienna, May 30, 1896.]

2 ['*Praeconsc*' in the MS. This term, apparently never used elsewhere by Freud, has, of course, quite a different meaning from '*vorbewusst*', for which the regular English translation is 'preconscious'.]

A and B (from about 8–10[1] and 13–17) are the transitional periods[2] during which repression for the most part occurs.

The arousal in a later epoch of a sexual memory from an earlier one [230]
produces a *surplus of sexuality* in the psyche which operates as an inhibition of thought and gives the memory and its consequences an obsessive character – uninhibitability.

The period I*a* possesses the characteristic of being *untranslated*,[3] so that the arousal of a I*a* sexual scene[4] leads, not to psychical consequences, but to *conversion*. The surplus of sexuality prevents translation.

Surplus of sexuality alone is not enough to cause repression; the cooperation of *defence* is necessary for it; but without a surplus of sexuality defence does not produce a neurosis.

The different neuroses have their particular chronological requirements for their sexual scenes [Fig. 6]:

Chronological requirements

	I*a*	I*b*	A	II	B	III
	up to 4	up to 8		up to 14		up to *x*
Hysteria	Scene		Repression		Repression	
Obs. Neur.		Scene	Repression		Repression	
Paranoia				Scene	Repression	

[Fig. 6]

That is, the scenes for hysteria occur in the first period of childhood (up to 4 years), in which the mnemic residues are not translated into verbal images [*Wortvorstellungen*][T]. It is a matter of indifference whether these I*a* scenes are aroused during the period after the second dentition (8–10) or in the stage of puberty. Hysteria always results and in the form of *conversion*, since the combined operation of defence and surplus of sexuality prevents translation.

The scenes for obsessional neuroses belong to Epoch I*b*. They are provided with a translation into words and when they are aroused in II or III, psychical obsessional symptoms are generated.

1 [The period of the second dentition, to which Freud attributed much importance at this time: see below, and cf. the second paper on the neuropsychoses of defence (1896*b*), *RSE*, **3**, 176 and 177 *n.* 1, and 'The Aetiology of Hysteria' (1896*c*), ibid., **3**, 217 f.]

2 [The forerunner of Freud's 'latency period' concept.]

3 [Into verbal images (see below).]

4 [The term 'sexual scene' is the forerunner of the 'primal scene' of later years. Cf. the 'Wolf Man' analysis (1918*b*), ibid., **17**, 35. In fact, 'primal scenes' appears only a year later than the present letter. See p. 274 below.]

The scenes for paranoia fall in the period after the second dentition, in
[231] Epoch II, and are aroused in III (maturity). In that case defence is manifested in disbelief. Thus the periods at which *repression* occurs are of no significance for the choice of neurosis,[1] the periods at which the *event* occurs are decisive. The *nature* of the scene is of importance insofar as it is able to give rise to defence. [Cf. pp. 270–1 below.]

What happens if the scenes extend over several periods? If so, the earliest epoch is decisive, or combined forms appear, which it should be possible to demonstrate. Such a combination is for the most part[2] impossible between paranoia and obsessional neurosis, because the repression of the I*b* scene effected during II makes fresh sexual scenes impossible. [Cf. Draft N, p. 282 below.]

Hysteria is the only neurosis in which symptoms are perhaps possible even without defence, for even so the characteristic of conversion would remain. (Pure somatic hysteria.)

It will be seen that paranoia depends the least on infantile determinants. It is the neurosis of defence *par excellence*, independent even of morality and aversion to sexuality which are what in A and B provide the motives for defence for obsessional neurosis and hysteria, and consequently accessible to the lower classes.[3] It is an affection of maturity. If there are no scenes in I*a*, I*b* or II, defence can have no pathological consequences (normal repression). The surplus of sexuality fulfils the preconditions for *anxiety attacks* during maturity. The memory traces are insufficient to take up the sexual quantity released, which should become [psychical] libido.

The importance of *intervals* between sexual experiences will be evident. A continuation of the scenes across a boundary between epochs may perhaps avoid the possibility of a repression, since in that case no surplus of sexuality arises between a scene and the first important memory of it.[4]

About consciousness [i.e. being conscious] or rather becoming conscious we must suppose three things:

[232] (1) that, as regards memories, it consists for the most part in the *verbal*

1 [This seems to be the first appearance of the actual term '*Neurosenwahl*'. Its first published use was much later – in a paper on the sexual aetiology of the neuroses (1906*a*), *RSE*, 7, 285.]

2 ['*Meist*' in the MS. Omitted in *Anf*., 176.]

3 ['*Daher dem niederen Plebs zugänglich*.' This clause is omitted in *Anf*., 176.]

4 [It may be recollected that according to Freud's current theory (p. 249 above) it was the interposition of puberty between an early sexual experience and the first memory of it that made neuroses possible.]

consciousness pertaining to them – that is, in access to the associated word presentations;[1]

(2) that it is not attached exclusively and inseparably either to the so-called unconscious or to the so-called conscious realm, so that these names seem to call for rejection;

(3) that it is determined by a *compromise* between the different psychical powers which come into conflict with one another when repressions occur.

These powers must be closely studied and inferred from their results.

They are (1) the *inherent quantitative strength* of a presentation and (2) a freely displaceable *attention* which is attracted according to certain rules and repelled in accordance with the rule of *defence*. Symptoms are almost all *compromise structures*.[2] A fundamental distinction is to be made between *uninhibited* and *thought-inhibited* psychical processes. It is in the conflict between these two that symptoms arise as compromises to which the path to consciousness is opened. In neuroses each of these two processes is in itself rational (the uninhibited one is mono-ideistic, one-sided); the resultant compromise is *irrational*, analogous to an error in thought.[3]

In every case *quantitative* conditions must be fulfilled, for otherwise the defence by the thought-inhibited process prevents the formation of the symptom.

One species of psychical disturbance arises if the power of the uninhibited processes increases; another if the force of the thought inhibition relaxes. (Melancholia, exhaustion – dreams as a prototype.)

An increase of the uninhibited processes to the point of being in sole possession of the path to verbal consciousness produces *psychosis*.

There is no question of a separation between the two processes; it is only considerations of unpleasure that bar the various possible associative transitions between them.

. . . . . .

1 [‘*Wortvorstellungen*.’ Freud had explained his theory of the part played in conscious thinking by speech associations in Part III of the ‘Project’ (p. 389 ff. below).]

2 [This had already been asserted in Draft K (e.g. pp. 251–2 and 254 above) and in the second paper on the neuropsychoses of defence (1896*b*), *RSE*, **3**, 179. For the ‘rule of defence’, see p. 394 below.]

3 [The distinction between the primary and secondary processes had already been drawn in the ‘Project’, p. 352 below. But the next few years were to clarify the distinction immeasurably as can be seen by comparing this passage with Chapter VII (E) of *The Interpretation of Dreams* (1900*a*). See, in particular, *RSE*, **5**, 534 ff.]

LETTER 50[1]

[233] . . . I must tell you a nice dream I had in the night after the funeral.[2] I was in some public place and read a notice there:

You are asked
to close the eyes.

I recognized the place at once as the barber's to which I go every day. On the day of the funeral I was kept waiting there and therefore reached the house of mourning rather late. At that time my family were displeased with me because I had arranged for the funeral to be quiet and simple, which they later agreed was quite right. They also took my being late in somewhat bad part. The sentence on the noticeboard has a double sense, and means in both of them: 'one should do one's duty to the dead.' (An apology, as though I had not done it and my conduct needed overlooking, and the duty taken literally.) Thus the dream is an outlet for the inclination to self-reproach[3] which is regularly present among the survivors.

. . . . . .

LETTER 52[4]

. . . As you know, I am working on the assumption that our psychical mechanism has come into being by a process of stratification: the material present in the form of memory traces being subjected from time to time to a *rearrangement* in accordance with fresh circumstances – to a *retranscription*. Thus what is essentially new about my theory is the thesis that memory is present not once but several times over, that it is laid down in various kinds of indications. I postulated a similar kind of rearrangement some time ago (*Aphasia*) for the paths leading from the [234] periphery [of the body to the cortex].[5] I cannot say how many of these registrations there are: at least three, probably more. This is shown in the following schematic picture [Fig. 7], which assumes that the different

1 [Dated Vienna, November 2, 1896. – The contemporary report of a dream which occurred soon after the death of Freud's father on October 23, 1896. This differs somewhat from the account in *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 283. From now onwards the letters begin to show more and more signs of occupation with the subject of dreams.]

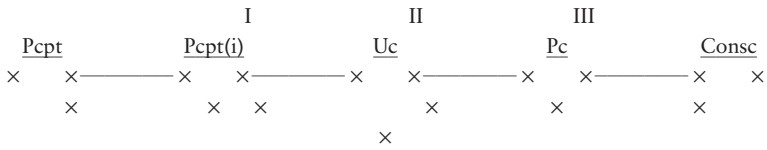
2 [In *The Interpretation of Dreams*, Freud assigns it to 'the night before my father's funeral'.]

3 [See footnote 2, p. 248 above.]

4 [Dated Vienna, December 6, 1896.]

5 [The reference is to a passage in Chapter V of Freud's monograph on aphasia (1891*b*), *NSW*, **4**. For precursors to the idea in Freud's anatomical writings, see p. 189 *n*. 1 above.]

registrations are also separated (not necessarily topographically) according to the neurons which are their vehicles.[1] This assumption may not be necessary, but it is the simplest and is admissible provisionally.



[Fig. 7]

Pcpt [*W*, *Wahrnehmungen* (perceptions)] are neurons in which perceptions originate, to which consciousness attaches, but which in themselves retain no trace of what has happened. For *consciousness and memory are mutually exclusive*.[2]

Pcpt(*i*) [*Wz*, *Wahrnehmungszeichen* (indication of perception)] is the first registration[3] of the perceptions; it is quite incapable of consciousness, and arranged according to associations by simultaneity.

Uc (*Ub*, *Unbewusstsein* [unconsciousness]) is the second registration, arranged according to other (perhaps causal) relations. *Uc* traces would perhaps correspond to conceptual memories; equally inaccessible to consciousness.

Pc ([*Vb*, *Vorbewusstsein*][4] preconsciousness) is the third transcription, attached to word presentations and corresponding to our official ego [*Ich*]^{T}. The cathexes [*Besetzungen*]^{T} proceeding from this *Pc* become conscious according to certain rules; and this secondary *thought consciousness* is subsequent in time, and is probably linked to the hallucinatory activation of word presentations, so that the neurons of [235]

1 [The laconic remark that the separation of the systems is not necessarily topographical foreshadows the radical notion of 'psychical locality', enunciated in Chapter VII of *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 478, leading to a purely functional dissection of the psychical apparatus. Figure 7 itself foreshadows the schematic pictures of the psychical apparatus in *The Interpretation of Dreams*, ibid., 480–3. The abbreviations used here also foreshadow the ones there, which first appear in Letter 64, and Draft N six months later than the present letter (pp. 280 and 282 below). *Consc* (*Bews*) stands for consciousness (*Bewusstsein*). The other abbreviations are explained in the text of this letter.]

2 [Breuer had pointed this out in *Studies on Hysteria* (1895*d*), *RSE*, **2**, 168 *n*., and Freud had elaborated on it in Part I, Section 3 of the 'Project', as well as elsewhere. (See p. 323 *n*. 1 below.) – At the end of the previous sentence, the MS. has '*des Geschehenen*'. *Anf*., 186, reads: '*des Geschehens*' ('of what happens').]

3 ['*Niederschrift*.' In the corresponding account in *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 481 f., the word used is '*Fixierung*', there translated 'record'. See Editors' footnote, p. 152 above. The implication is that this is a *memory* system.]

4 [This is the first known appearance of the term. Its first published occurrences were in *The Interpretation of Dreams*, *RSE*, **4**, 301, and **5**, 447.]

consciousness would once again be perceptual neurons and in themselves without memory.

If I could give a complete account of the psychological characteristics of perception and of the three registrations, I should have described a new psychology. Some material for this is in my hands, but that is not my present intention.

I should like to emphasize the fact that the successive registrations represent the psychical achievement [*Leistung*] of successive epochs of life. At the frontier between two such epochs a translation [*Übersetzung*][T] of the psychical material must take place. I explain the peculiarities of the psychoneuroses by supposing that this translation has not taken place in the case of some of the material, which has certain consequences. For I hold firmly to a belief in a trend towards quantitative[1] adjustment. Every later transcript inhibits its predecessor and drains off the excitatory process from it. If a later transcript is lacking, the excitation is dealt with in accordance with the psychological laws in force in the earlier psychical period and along the paths open at that time. Thus an anachronism persists: in a particular province *fueros*[2] are still in force, we are in the presence of 'survivals'.

A failure[t] of translation – this is what is known clinically as 'repression'.[3] The motive [*Motiv*][T] for it is always a release of unpleasure which would be generated by a translation; it is as though this unpleasure provokes a disturbance of thought which does not permit the work of translation.

Within one and the same psychical phase, and among registrations of the same species, a *normal* defence makes itself felt owing to a generation of unpleasure. But *pathological* defence only occurs against a memory trace from an earlier phase which has not yet been translated.

It cannot be due to the *magnitude* of the release of unpleasure if the defence succeeds in bringing about repression. We often struggle in vain precisely against memories involving the greatest unpleasure. So we arrive at the following account. If an event *A*, when it was a current one, aroused a certain amount of unpleasure, then the mnemic registration of it, *A* I or *A* II, possesses a means of inhibiting the release of unpleasure
[236] when the memory is reawakened. The more often the memory recurs, the more inhibited does the release finally become.[4] There is *one* case,

1 ['*Quantitativen*' in the MS. *Anf.*, 187, has '*qualitativen*'.]

2 [A *fuero* was an ancient Spanish law holding good in some particular city or province and guaranteeing that region's immemorial privileges.]

3 [Cf. footnote 1, p. 297 below.]

4 [Cf. the discussion of the 'taming' of memories in Section 3 of Part III of the 'Project' (p. 404 ff. below).]

however, in which the inhibition is insufficient. If *A*, when it was current, released a particular unpleasure and if, when it is reawakened, it releases fresh unpleasure, then this cannot be inhibited. If so, the memory is behaving as though it were some current event. This case can only occur with sexual events, because the magnitudes of the excitations which these release increase of themselves with time (with sexual development).

Thus a sexual event in one phase acts in the next phase as though it were a current one and is accordingly uninhibitable. What determines pathological defence (repression) is therefore *the sexual nature of the event and its occurrence in an earlier phase*.

Not all sexual experiences release unpleasure; most of them release pleasure. Thus the reproduction of most of them is linked with uninhibitable pleasure. An uninhibitable pleasure of this kind constitutes a *compulsion* [*Zwang*]. We are therefore led to the following theses. If a sexual experience is remembered in a different phase, a release of pleasure is accompanied by compulsion and a release of unpleasure by repression. In both cases the translation into the indications of the new phase seems to be inhibited (?).[1]

Now, clinical experience makes us acquainted with three groups of sexual psychoneuroses – hysteria, obsessional neurosis and paranoia; and it teaches us that the repressed memories relate to what was current in the case of hysteria between the ages of 1½ and 4, of obsessional neurosis between 4 and 8, and of paranoia between 8 and 14. But before the age of 4 there is no repression yet; so that the psychical periods of development and the sexual phases do not coincide. [Fig. 8.]

	1½	4	8	14–15	
Psych.	Ia		Ib	II	III
Sex.	I			II	III

[Fig. 8]

The following small diagram has its place here [Fig. 9, overleaf]. For another consequence of premature sexual experiences is perversion, of which the determinant seems to be that defence either did not occur before the psychical apparatus was completed or did not occur at all. [238]

So much for the superstructure. Now for an attempt to set it on its organic foundations.[2] What has to be explained is why sexual

1 [The question mark is in the MS.]

2 [Cf. Freud's remark in *The Interpretation of Dreams* to the effect that he sees no harm in a purely functional dissection of the psychical apparatus, so long as we 'do not mistake the scaffolding for the building' (1900*a*), *RSE*, **5**, 479.]

[Fig. 9][1]

1 [The abbreviations used here are explained on p. 261 above.]

experiences, which, when they were current, generated pleasure, should, when they are remembered from a different phase, generate unpleasure in some people and persist as compulsion in others. In the former case they must evidently be releasing at a later time an unpleasure which was not released to begin with.

We have also to trace the derivation of the different epochs, psychological and sexual. You have explained the latter to me as special multiples of the 28-day female period. . . .[1]

. . . . . .

In order to account for why the outcome [of premature sexual experience (see above)] is sometimes perversion and sometimes neurosis, I avail myself of the bisexuality of all human beings. In a purely male being there would be a surplus of male release at the two sexual barriers[2] as well – that is, pleasure would be generated and consequently perversion; in purely female beings there would be a surplus of unpleasurable substance at these times. In the first phases the releases would be parallel: that is, they would produce a normal surplus of pleasure. This would explain the preference of true females for neuroses of defence.

In this way the intellectual nature of males would be confirmed on the basis of your theory.

Finally, I cannot suppress a suspicion that the distinction between neurasthenia and anxiety neurosis, which I detected clinically, is connected with the existence of the two 23-day and 28-day substances.

Besides the two which I suspect here, there might be several of each kind.[3]

It seems to me more and more that the essential point of hysteria is that it results from *perversion* on the part of the seducer, and *more and more* [239] that heredity is seduction by the father. Thus an alternation emerges between generations:

1st generation: Perversion.

2nd generation: Hysteria, and consequent sterility. Occasionally there is a metamorphosis within the same individual: perverse during the age of strength and then, after a period of anxiety, hysterical. Accordingly, hysteria is not repudiated sexuality but rather *repudiated perversion*.

1 [At this point we follow the editors of *Anf.* in omitting a long passage (two pages of the MS.), only intelligible in the light of Fliess's theory of periodicity.]

2 [See the double lines in Fig. 8.]

3 [See footnote 2, p. 346 below.]

Furthermore, behind this lies the idea of abandoned *erotogenic zones*.[1] That is to say, during childhood sexual release would seem to be obtainable from very many parts of the body, which at a later time are only able to release the 28[-day] anxiety substance and not the others. In this differentiation and limitation [would thus lie] progress in culture
Kultur [*Kulturfortschritt*][T], moral as well as individual development.

A hysterical attack is not a discharge but an *action*; and it retains the original characteristic of every action – of being a means to the reproduction of pleasure. (That, at least, is what it is at root; apart from this it puts forward all kinds of other[2] reasons to the preconscious.) Thus patients who have had something sexual done to them in *sleep* have attacks of sleep. They go to sleep again in order to experience the same thing and often provoke a hysterical fainting fit in that way.

Attacks of giddiness and fits of weeping – all these are aimed at *another person* – but mostly at the prehistoric, unforgettable other person who is never equalled by anyone later. Even the chronic symptom of a pathological desire to stay in bed is explained in the same way. One of my patients still whimpers in his sleep as he used to do – to be taken into bed by his mother, who died when he was 22 months old. Attacks never seem to occur as an 'intensified expression of emotion'.[3]

. . . . . .

LETTER 55[4]

[240] . . . I am sending you, red hot, two ideas which occurred to me today and which seem to me to be viable. They are based, of course, on analytic findings.

(1) What determines a psychosis (that is to say, amentia or a confusional psychosis – a psychosis of overwhelming, as I called it before[5]) instead of a neurosis seems to be that sexual abuse should occur before the end of the first intellectual stage – i.e. before the psychical apparatus has been

1 [Apparently the first appearance of this concept. Freud made it public in his *Three Essays on the Theory of Sexuality* (1905*d*), *RSE*, **7**, 149 ff.]

2 ['*Anderen*' in the MS. Omitted in *Anf.*, 192.]

3 [In his first paper on the neuropsychoses of defence (1894*a*), Freud had been inclined to accept this definition of hysteria put forward by Oppenheim (1890). See *RSE*, **3**, 48 and *n.* 1.]

4 [Dated Vienna, January 11, 1897.]

5 [Cf. p. 250 *n.* 2 above. An example of its occurrence is mentioned in the first paper on the neuropsychoses of defence (1894*a*), *RSE*, **3**, 51 f.]

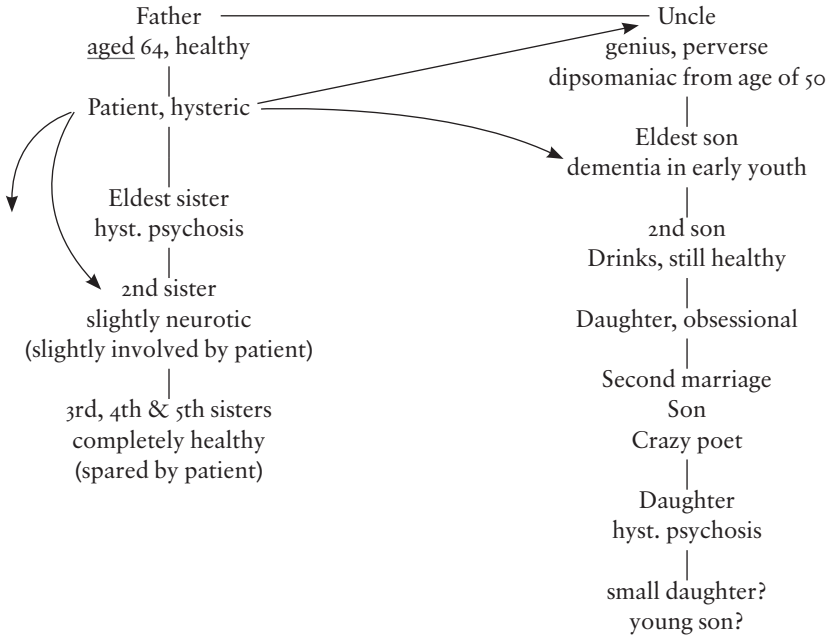
completed in its first form (before 15 to 18 months).[1] It is possible that the abuse may date back so far that these experiences may lie concealed behind the later ones, and that they may be returned to from time to time. Epilepsy, I believe, goes back to the same period. . . . I shall have to deal differently with *tic convulsif*, which I used to assign to the same stage. This is how I arrived at this. One of my male hysterical patients (my millionaire) sent his eldest sister into a hysterical psychosis which ended in a state of complete confusion. I have now traced his own seducer, a man of genius who, however, had had attacks of the severest dipsomania from his fiftieth year onwards. These attacks regularly started either with diarrhoea or with catarrh and hoarseness (the oral sexual system!) – that is, with the reproduction of his own passive experiences. Now, until he fell ill himself, the man had been a pervert and consequently healthy.[2] The dipsomania arose through the strengthening – or rather through the *substitution* of the one impulse for the associated sexual one. (The same is probably true of the gambling mania of old F.)[3] Now scenes took place between this seducer and my patient, in some of which his little sister, who was less than a year old, took part. My patient had relations with her later on and she became psychotic at puberty. You may gather from this how a neurosis increases to a psychosis in the next generation (this is what people call 'degeneracy') simply because someone of a more tender age is drawn in. Here, by the way, is the heredity of this case [Fig. 10]:

1 [The seduction hypothesis was ascendant in Freud's thinking at this time. Cf. Letter 59, p. 271 below. The hypothesis is withdrawn in Letter 69 (p. 286 below).]

2 [I.e. not neurotic. See p. 265 above.]

3 [Cf. some remarks on addictions below, p. 298 and *n.* 2.]

[241]



[Fig. 10]

I hope I shall be able to tell you much else of importance about this case, which throws light on three forms of illness.

(2) The perversions regularly lead into zoophilia, and have an animal character. They are explained not by the functioning of erotogenic zones which have later been abandoned, but by the effect of erotogenic *sensations* which lose this force later. In this connection it will be recalled that the principal sense in animals (for sexual as well as other purposes) is that of smell, which has lost that position in human beings. So long as smell (or taste) is dominant, urine, faeces and the whole surface of the body – and blood as well – have a sexually exciting effect. The heightened sense of smell in hysteria is no doubt connected with this. The fact that the groups of sensations have much to do with psychological stratification seems to follow from their distribution in dreams and no doubt has a direct connection with the mechanism of hysterical anaesthesia.[1]

. . . . . .

1 [These ideas are expanded in Letter 75, p. 294 below, where references can be found to later discussions of the subject by Freud.]

LETTER 56[1]

. . . What would you say, by the way, if I told you that the whole of my [242]
brand-new primal history of hysteria was already well known and had been published a hundred times over – several centuries ago? Do you remember how I always said that the mediaeval theory of possession, held by the ecclesiastical courts, was identical to our theory [Freud & Breuer, 1895*d*] of a foreign body and a splitting of consciousness?[2] But why did the Devil, who took possession of the poor wretches, invariably defile them, and in a revolting manner? Why are their confessions under torture so like the communications made by my patients in psychical treatment? Some time soon I must delve into the literature of the subject. Incidentally, the cruelties make it possible to understand some symptoms of hysteria which have hitherto been obscure. The pins which appear in the most astonishing ways, the needles on account of which the poor things have their breasts cut open but which are invisible by X-rays though they can no doubt be found in their stories of seduction . . .

Once more the inquisitors prick with needles, to discover the Devil's stigmata, and in a similar situation the victims invent[t] the same old cruel story (helped perhaps by the seducer's disguises). Thus, not only the victims but the executioners recalled in this their earliest youth.

. . . . . .

LETTER 57[3]

. . . The idea of bringing in the witches is gaining strength, and I think it hits the mark. Details are beginning to crowd in. Their 'flying' is explained; the broomstick they ride on is probably the great Lord Penis. Their secret gatherings, with dancing and other amusements, can be seen any day in the streets where children play. I read one day that the [243]
gold which the Devil gives his victims regularly turns into faeces; and the

1 [Dated Vienna, January 17, 1897. – In this letter and the next one Freud was making a first major incursion into the field of anthropology, and was also further developing (what had started in the last letter) his understanding of the psychological importance of anal material.]

2 [Freud had already commented on this in his obituary of Charcot (who had himself made frequent references to mediaeval witchcraft). Cf. Freud (1893*f*), *NSW*, **4**; *RSE*, **3**, 19. He returned to the subject in his analysis of 'A Seventeenth-Century Demonological Neurosis' (1923*d*), ibid., **19**, 63.]

3 [Dated Vienna, January 24, 1897.]

next day Herr E.,[1] who describes his old nurse's money deliria[2] to me, suddenly (by a roundabout path via Cagliostro – alchemist – *Dukatenscheisser*[3]) said that Louise's money was always faeces. So in the witch stories it is merely being transformed back into the substance from which it arose. If only I knew why the Devil's semen is always described as 'cold' in the witches' confessions! I have ordered a copy of *Malleus Maleficarum* and, now that I have put the final touch to my *Kinderlähmungen*, I shall study it diligently.[4] The story of the Devil, the vocabulary of popular swear words, the songs and habits of the nursery – all these are now gaining significance for me. Can you without trouble recommend me some good reading from your well-stocked memory? In connection with the dancing in witches' confessions, remember the dance epidemics in the Middle Ages. E.'s Louise was a dancing witch of that kind; he was first, consistently enough, reminded of her at the ballet: hence his theatre anxiety.

Alongside of flying and floating on the air are to be put the gymnastic feats of boys in hysterical attacks, etc.

I have an idea shaping in my mind that in the perversions, of which hysteria is the negative,[5] we may have before us a residue of a primaeval sexual cult which, in the Semitic East (Moloch, Astarte), was once, perhaps still is, a religion. . . .

Perverse actions, moreover, are always the same – with a meaning and made on some pattern which it will be possible to understand.

I dream, therefore, of a primaeval Devil religion, whose rites are carried on secretly, and I understand the severe therapy of the witches' judges. The connecting links abound.

[244] Another tributary to the stream is derived from the consideration that there is a class of people who to this very day tell stories like those of the witches and of my patients; they find no belief, though their own belief in them is not to be shaken. As you have guessed, I mean the paranoics,

1 [A very long-standing patient of this period (referred to in the Editors' Note to 'Analysis Terminable and Interminable' (1937*c*), *RSE*, **23**, 194). His 'nurse and first love' (as he called her) was a Frenchwoman named Louise.]

2 [See footnote 3, p. 299 below.]

3 [Literally 'shitter of ducats', slang for a wealthy spendthrift. Freud included this (and some of the other points in this letter) in his paper on 'Character and Anal Erotism' (1908*b*), *RSE*, **9**, 152 f.]

4 [The fifteenth-century work 'The Hammer of Evil-doing Women' (by Sprenger & Kraemer) on mediaeval witches. – *The Infantile Cerebral Palsies* (1897*a*; *NSW*, **3**) was Freud's last purely neurological book.]

5 [This parenthetical remark, which is already hinted at above (pp. 265 f. and 267), is constantly repeated (in the form 'neuroses are the negative of perversions') in Freud's later works. See, for instance, the *Three Essays* (1905*d*), *RSE*, **7**, 147.]

whose complaints that people put faeces in their food, ill-treat them at night in the most abominable way, sexually, etc., are pure content of the memory.[1] As you know, I have distinguished between delusions of memory and interpretative delusions [p. 254 *n*. 3 above]. The latter are connected with the characteristic indefiniteness concerning the evil-doers, who, of course, are concealed by the defence.

One more detail. In hysterical patients I recognize their father behind their high standards in love, their humility towards their lover or their being unable to marry because their ideals are unfulfilled. The basis for this is, of course, the height from which a father looks down on a child. Compare with this the combination in paranoics of megalomania with fictions of an alienation of parentage.[2] That is the reverse side of the medal.

At the same time, I am becoming less certain about a suspicion I have hitherto been entertaining that the choice of neurosis is determined by the period at which it originates; it seems rather to be fixed in earliest childhood. But the decision seems to keep on oscillating between the period at which it originates and (what I prefer at present) the period at which repression occurs. [Cf. p. 258 above.]

. . . . . .

LETTER 59[3]

. . . The point that escaped me in the solution to hysteria lies in the discovery of a new source from which a new element of unconscious production arises. What I have in mind are hysterical phantasies [*Phantasien*][T], which regularly, as it seems to me, go back to things heard by children at an early age and only understood later. The age at which they take in information of this kind is very remarkable – from the age of six to seven months onwards! . . .[4] [245]

. . . . . .

1 [This idea often recurs in Freud's later writings. See, for instance, *The Psychopathology of Everyday Life* (1901*b*), *RSE*, **6**, 220, where, in an Editors' footnote, a number of other references are given.]

2 [At this early period Freud seems to have been inclined to restrict these phantasies to paranoics. But before long he extended their field to neurotics in general and found a new name for them – 'Family Romances'. See pp. 280 and 292 below, and the paper with that title (1909*c*), *RSE*, **9**, 211 f.]

3 [Dated Vienna, April 6, 1897.]

4 [Cf. the 'Wolf Man's' observation of his parents' intercourse at the age of one and a half years (1918*b*), ibid., **17**, 108 *n*.]

LETTER 60[1]

. . . I had a dream last night which was concerned with you. It was a telegraph message about your whereabouts:

'(Venice) Via / Villa Casa SECERNO'

The way I have put it shows what seemed obscure and what seemed multiple. 'Secerno' was what was clearest. My feeling about it was annoyance that you had not gone where I had recommended you: to Casa Kirsch.[2]

The dream's motives. – The provoking cause: events from the previous day. H. was here and talked about Nuremberg, saying he knew it very well and used to stay at the Preller. I could not recall it at once, but afterwards I asked: 'Outside the town, then?' This conversation stirred up the regret I have felt lately at not knowing where you are stopping and having no news of you. I wanted to have you as my public and to tell you some of what I have been experiencing and finding out in my work. But I did not dare to send my notes out into the unknown, as I should have wanted to ask you to keep them for me as material of value. So it is the fulfilment of a wish if you telegraph your address to me. There are all kinds of things behind the wording of the telegram: the memory of the etymological enjoyment you usually give me, my mention of 'outside the town' to H., but more serious things as well, which soon occurred to me. 'As though you must always have something special!'[3] says my annoyance. And then that you take no pleasure at all in the Middle Ages.[4] And further, my continued reaction to your dream of defence, which tried to
[246] substitute a grandfather for the otherwise current father. In that connection, my constantly bothering myself as to how I can give you a hint to find out who it was who called I.F.[5] '*Katzel*' [kitten] when she was a child, as she now calls you. Since I myself am still in doubt about matters concerning fathers, my sensitiveness becomes understandable. Thus the dream collects together all the annoyance with you that is unconsciously present in me.

1 [Dated Vienna, April 28, 1897. – A very much shorter account of this dream is included in *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 282.]

2 [A pension in Venice.]

3 [Perhaps that the pension recommended by Freud was not good enough for him.]

4 [Fliess seems not to have appreciated the mediaeval architecture of Nuremberg.]

5 [Fliess's wife, Ida.]

Moreover, the wording means still more:

Via (streets in Pompeii, which I am studying).
Villa (Böcklin's Roman Villa).

Our talks about travel, then. Secerno[1] sounds to me like Salerno: Neapolitan – Sicilian. And behind it your promise of a meeting on Italian soil.

The complete interpretation [*Deutung*][T] only occurred to me after a lucky chance this morning brought a fresh confirmation of paternal aetiology. Yesterday I began the treatment of a new case: a young woman whom, for lack of time, I would have preferred to scare off. She had a brother who died insane; and her main symptom (insomnia) first appeared after she had heard the carriage that was taking him to the asylum drive away from the front door. Since then she has suffered from anxiety at driving and a conviction that there would be a carriage accident. Years later, the horses bolted during a drive and she took the opportunity of jumping out of the carriage and breaking her foot. She came today and confessed that she had thought a lot about the treatment and had discovered an obstacle. 'What was that?' – 'I can make myself out as bad as I must; but I must spare other people. You must allow me to name no names.' – 'No doubt names are not important. What you mean are your relations to the people. That can certainly not be hushed up.' – 'What I mean is that altogether I should have been easier to treat earlier than today. Earlier I was unsuspecting; but now the criminal meaning of some things has become clear to me and I cannot make up my mind to talk about them.' – 'On the contrary, I think a mature woman becomes more tolerant about sexual matters.' – 'Yes, you are right there. When I say to myself that the people who do such things are excellent and noble, I am bound to reflect that it is a disease, a kind of madness, and I must excuse them.' – 'Well then, let us speak plainly. In my analyses the guilty people are close relatives, a father or a [247]
brother.' – 'There is no question of a brother.' – 'Your father, then.'

And it then turned out that her supposedly otherwise noble and respectable father regularly took her to bed when she was from 8 to 12 years old and misused her without penetrating ('made her wet', nocturnal visits). She felt anxiety even at the time. A sister, six years her senior, had told her years afterwards that she had had the same experiences with their father. A cousin told her that when she was 15 she had had to fend off her grandfather's embraces. Of course, when I told her that similar

1 [In *The Interpretation of Dreams* (1900*a*), the further point is made that '*Secerno*' is etymologically related to secrecy and seclusion.]

and worse things must have happened in her earliest childhood, she could not find it incredible. In other ways it is a quite ordinary case of hysteria with the usual symptoms.

Q.E.D.

. . . . . .

LETTER 61[1]

. . . As you will gather from the enclosure [Draft L], my gains are becoming consolidated. In the first place, I have gained a sure notion of the structure of hysteria. Everything goes back to the reproduction of scenes, some of which can be arrived at directly, but others always by way of phantasies set up in front of them. The phantasies are derived from things that have been *heard* but understood *subsequently* [*nachträglich*] and all their material is, of course, genuine. They are protective structures, sublimations[2] of the facts, embellishments of them, and at the same time serve for self-exoneration. Their precipitating origin is perhaps from masturbation phantasies. A second important
Bildung piece of insight tells me that the psychical structures [*Gebilde*][T] which, in hysteria, are affected by repression are not in reality memories – since no-one indulges in mnemic activity without a motive – but *impulses*[3] which arise from the primal scenes [see p. 257 above].[4] I realize now that all three neuroses (hysteria, obsessional neurosis and paranoia) exhibit the same elements (along with the same aetiology) – namely, mnemic
[248] fragments, *impulses* (derived from the memory) and *protective fictions*, but that the breakthrough into consciousness, the formation of compromises (that is, of symptoms), occurs in them at different points. In hysteria the memories, in obsessional neurosis the perverse impulses, in paranoia the protective fictions (phantasies), are what penetrate into normal life distorted by compromise.

In this I see a great advance in insight. I hope it strikes you in the same way.

. . . . . .

1 [Dated Vienna, May 2, 1897.]

2 [This term does not seem to appear in its later, psychoanalytic, sense until the 'Dora' case history (1905*e* [1901]), *RSE*, 7, 46, and the *Three Essays* (1905*d*), ibid., 7, 158 f.]

3 ['*Impulse*.' See footnote 4, p. 281 below.]

4 [Although the 'primal scenes' in question are still conceived of as historical events here, there seems to be a hint at a beginning of the 'dynamic' theory of the causation of neuroses (and beyond that of mental processes in general).]

DRAFT L[1]
[NOTES I]

The Architecture of Hysteria

The aim seems to be to arrive [back] at the primal scenes. In a few cases this is achieved directly, but in others only by a roundabout path, via phantasies. For phantasies are psychical façades constructed in order to bar the way to these memories.[2] Phantasies at the same time serve the trend towards refining the memories, towards sublimating them. They are made up from things that are *heard*, and made use of *subsequently* [*nachträglich*]; thus they combine things that have been experienced and things that have been heard, past events (from the history of parents and ancestors) and things that have been seen by oneself. They are related to things heard, as dreams are related to things seen. In dreams, to be sure, we hear nothing, but we see.

The Part Played by Servant Girls

An immense load of guilt, with self-reproaches (for theft, abortion, etc.), is made possible [for a woman] by identification[3] with these people of low morals, who are so often remembered by her as worthless women [249] connected sexually with her father or brother. And, as a result of the sublimation of these girls in phantasies, most improbable charges against other people are made in these phantasies. Fear of prostitution [i.e. of becoming a prostitute] (fear of being in the street alone), fear of a man hidden under the bed, etc., also point in the direction of servant girls. There is tragic justice in the fact that the action of the head of the family in stooping to a servant girl is atoned for by his daughter's self-abasement.

1 [Enclosed in Letter 61 (above), dated May 2, 1897. – Freud was in the habit all through his life of noting down from day to day disconnected thoughts as they occurred to him. Drafts M and N are other examples. And something similar has survived from the very last days of his life (1941*f* [1938]), *RSE*, **23**, 274 ff. For a full appreciation of the role these notes played in Freud's writings, see Grubrich-Simitis, 1993, Part II.6.]

2 [A much more elaborate version of this account of the function of phantasies is given in Chapter VI (I) of *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 439–42.]

3 [Cf. an Editors' footnote on Freud's use of this word in *The Interpretation of Dreams*, ibid., **4**, 134 *n*. It had already been used in Letter 58 (not included here) of February 8, 1897, and appears in several later letters of this period, and especially in Letter 125 (p. 306 below).]

Mushrooms

There was a girl last summer who was afraid to pick a flower or even to pull up a mushroom, because it was against the command of God, who did not wish living seeds to be destroyed. – This arose from a memory of religious scruples of her mother's directed against precautions during coitus, because they mean that living seeds are destroyed. 'Sponges' (Paris sponges)[1] were explicitly mentioned among these precautions. The main content of her neurosis was identification with her mother.

Pains

These are not an actual sensation of a fixation, but an intentional repetition of it. The child knocks up against a corner, a piece of furniture, etc., and so makes contact *ad genitalia*, in order to repeat a scene in which what is now the painful spot and was then pressed against the corner led to fixation. [Cf. footnote, p. 152 above.]

Multiplicity of Psychical Personalities

The fact of identification perhaps allows us to take the phrase *literally*.

Wrapping up

A continuation of the mushroom story. The girl insisted that any objects handed to her must be wrapped up. (Condom.)[2]

Multiple editions of phantasies – do they also connect back again [to the original experience]?

In cases in which a patient *wishes* to be ill and clings to his ailment, this regularly happens because the ailment is regarded as a protective weapon against his own libido – that is, because he mistrusts himself. In this phase
[250] the mnemic symptom becomes a defensive symptom: the two active currents combine. At earlier stages the symptom was a consequence of the libido, a provocative symptom: it may be that between the stages phantasies serve for defence.

1 [A form of contraceptive. The German word '*Schwämme*' means both 'mushrooms' and 'sponges'.]

2 [The following three notes lack headings, and were therefore erroneously combined into a single note in *Anf.* and *SE*.]

It is possible to follow the path, the time and the material of the formation of phantasies [*Phantasiebildung*]. It is then seen closely to resemble the formation of dreams. But there is no regression in the form [of representation] phantasies are given, only progression. Note the relation between dreams, phantasies and reproduction.[1] *Bildung*

Another Wishful Dream

'You will say, I suppose, that this is a wishful dream,' said E. [p. 270 *n*. 1 above]. 'I dreamt that, just as I arrived at my house with a lady, I was arrested by a policeman, who ordered me to get into a carriage. I asked for time to put my affairs in order, and so on.' – 'Some more details.' – 'It was in the morning, after I had spent the night with this lady.' – 'Were you horrified?' – 'No.' – 'Do you know what you were charged with?' – 'Yes. With having killed a child.' – 'Has that any connection with reality?' – 'I was once responsible for the abortion of a child resulting from a liaison. I dislike thinking about it.' – 'Well, had nothing happened on the morning before the dream?' – 'Yes, I woke up and had intercourse.' – 'But you took precautions?' – 'Yes. By withdrawing.' – 'Then you were afraid you might have procreated a child, and the dream shows you the fulfilment of your wish that nothing happened and that you nipped the child in the bud. You made use of the feeling of anxiety that arises after a coitus of that kind as material for your dream.'[2]

DRAFT M[3]
[NOTES II]

The Architecture of Hysteria

It is probably like this: some of the scenes are accessible directly, but others only by way of phantasies set up in front of them.[4] The scenes are arranged in the order of increasing resistance: the more slightly repressed ones come to light first, but only incompletely on account of their association with the severely repressed ones. The path taken by [analytic] work first goes down in loops to the scenes or to their neighbourhood; [251]

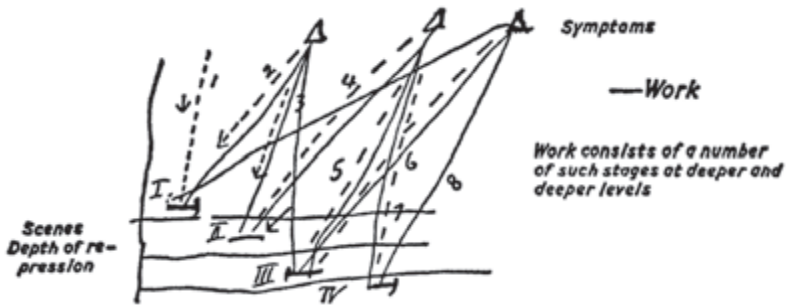
1 [It can be seen from this that Freud had already arrived at some of the main lines of his theory of dreams.]

2 [A very much fuller account of this dream (attributed there 'not to a patient, but to an intelligent jurist of my acquaintance') is given in Chapter IV of *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 137–9.]

3 [Enclosed in Letter 63 (not included here) dated Vienna, May 25, 1897.]

4 [Cf. Letter 61, p. 274 above.]

then from a symptom a little deeper down, and then again from a symptom deeper still. Since most of the scenes converge on the few symptoms, our path makes repeated loops through the background thoughts of the same symptoms. [See Fig. 11.]



[Fig. 11][1]

Repression

It is to be suspected that the element essentially responsible for repression is always what is feminine. This is confirmed by the fact that women as well as men admit more easily to experiences with women than with men. What men essentially repress is the paederastic element.[2]

Phantasies

[252] Phantasies arise from an unconscious combination, in accordance with certain trends, of things experienced and heard. These trends are towards making inaccessible the memory from which the symptoms have emerged or might emerge. Phantasies are constructed [*Phantasiebildung*] by a process of amalgamation and distortion analogous to the decomposition of a chemical body which is compounded with another one. For the first sort of distortion consists in a falsification of memory by a process of fragmentation in which chronological relations in particular are

1 [The words at the left of this figure, '*Szenen*' and '*Tiefe der Verdrängung*', are omitted from the reproduction in *Anf.*, 217. All dotted lines, arrows and numbers are in red in the original as well as the prominent word '*Arbeit*' ('work') and the line before it. The remaining words at the right of the figure are removed in *Anf.* from their present position and included in the text (p. 216).]

2 [Freud seems here to be inclining towards a 'sexualization of the process of repression', a view which he was already to abandon in Letter 75, p. 297 below, and against which he so often argued in his later writings. See, in particular, the last paragraphs in '"A Child is Being Beaten"' (1919*e*), *RSE*, **17**, 194 ff. Of the two theories criticized there, the present view seems to resemble that of Adler rather than that of Fliess. See also, however, the end of 'Analysis Terminable and Interminable' (1937*c*), ibid., **23**, 226 ff.]

neglected. (Chronological corrections seem precisely to depend on the activity of the system of consciousness.)[1] A fragment of the visual scene is then joined up with a fragment of the auditory one and made into the phantasy, while the fragment left over is linked up with something else. In this way it is made impossible to trace an earlier connection. As a result of the formation of phantasies like this (in periods of excitation) the mnemic symptoms cease. Instead, unconscious fictions are present which are not subjected to defence. If now the intensity of such a phantasy increases to a point at which it would be bound to force its way into consciousness, it is repressed and a symptom is generated through a backward impetus [*Rückdrängung*] from the phantasy to its constituent memories.

All anxiety symptoms (phobias) are derived in this way from phantasies. Nevertheless, this simplifies symptoms. There may perhaps be a third movement forward and a third method of symptom-formation derived from the formation of impulses.[2]

Kinds of Compromise Displacement

Displacement by association: hysteria.
Displacement by (conceptual) similarity: obsessional neurosis.
Causal displacement: paranoia.

Characteristic of the place at which the defence occurs (and perhaps also of the time).[3]

Typical Passage of Events

Good grounds for suspecting that the arousing of the repressed is not left to chance but follows the laws of development. Further, that repression proceeds backwards from what is recent, and affects the latest events first. [253]

Difference between the Phantasies in Hysteria and Paranoia

The latter are systematic, all of them in harmony with one another; the former are independent of one another and contradictory – insulated,

1 [This and a passage below (and p. 280) seem like early hints at Freud's later theory of the 'timelessness' of the unconscious and of one of the functions of the preconscious system being to give mental events an order in time. See, for instance, Section V of the paper on 'The Unconscious', *RSE*, **14**, 165–6.]

2 ['*Impulsbildung*' in the MS. *Anf*., 218, has simply '*Impulsen*'. – See p. 274, footnotes 3 and 4 above.]

3 [This sentence was mislocated in *Anf*. and therefore in *SE*.]

that is, and, as it were, automatically generated (by a chemical process). This and neglect of the characteristic of time are no doubt essential for the distinction between activity in the preconscious and unconscious. [See footnote 1, p. 279 above.]

Repression in the Unconscious

It is not sufficient to take into account the repression between the preconscious and the unconscious; we must also consider the normal repression within the system of the unconscious itself. Very important, but still very obscure.[1]

There is the highest hope of our being able to determine the number and kind of phantasies just as we can with scenes. A romance of alienation (cf. paranoia [p. 271 above]) is found regularly, and serves as a means of bastardizing the relatives in question. Agoraphobia seems to depend on a romance of prostitution, which itself goes back once more to this family romance. Thus a woman who will not go out by herself is asserting her mother's unfaithfulness.

LETTER 64[2]

. . . Here are a few fragments cast up on the beach at the last tide. I am noting them down for you alone and hope you will keep them for me. I add nothing[3] by way of apology or explanation: I know that they are only premonitions; but something has come of everything of the sort, and I have only had to take back what I tried to elaborate around the system *Pcs*. [Cf. p. 282 *n*. 5 below.] Another presentiment, too, tells me, as I knew already – though in fact I know nothing at all – that I shall very soon discover the source of morality. . . .

[254] Not long ago I dreamt of having overaffectionate feelings towards Mathilde,[4] only she was called Hella and afterwards I again saw 'Hella' before me printed in heavy type. Solution: Hella is the name of an American niece whose picture we have been sent. Mathilde could be called Hella because she has recently wept so much over the Greek defeats.[5] She

1 [The following note (which lacks a heading) is not part of the present note, as suggested in *Anf*. and *SE*.]

2 [Dated Vienna, May 31, 1897.]

3 ['*Nichts*' in the MS. is omitted in *Anf*., 219.]

4 [Freud's eldest daughter, aged 11 at that time.]

5 [This was the year of the Greco-Turkish War, in which the Greeks suffered many defeats.]

is enthusiastic about the mythology of ancient Hellas and naturally regards all Hellenes as heroes. The dream of course shows the fulfilment of my wish to catch a *Pater* as the originator of neurosis, and so to put an end to my doubts about this which still persist.[1]

Another time I dreamt that I was going up a staircase with very few clothes on. I was moving, as the dream explicitly emphasized, with great agility (my heart – reassurance!). Suddenly I noticed, however, that a woman was coming after me and thereupon the experience set in, so common in dreams, of being glued to the spot, of being paralysed. The accompanying feeling was not anxiety but an erotic excitation [*Erregung*]. So you see how the sensation of paralysis characteristic of sleep was used for the fulfilment of an exhibitionistic wish. Earlier that night I had in fact gone up the staircase from our ground-floor flat – without a collar at any rate – and had thought that one of our neighbours might be on the stairs.[2]

. . . . . .

DRAFT N[3]
[NOTES III]

Impulses[4]

Hostile impulses against parents (a wish that they should die) are also an integral constituent of neuroses. They come to light consciously as obsessional ideas. In paranoia what is worst in delusions of persecution [255]
(pathological distrust of rulers and monarchs) corresponds to these impulses. They are repressed at times when compassion for the parents is active – at times of their illness or death. On such occasions it is a manifestation of mourning to reproach oneself for their death (what is known as melancholia) or to punish oneself in a hysterical fashion (through the medium of the idea of retribution) with the same states [of illness] that they have had. The identification which occurs here is, as we can see,

1 [His doubts triumphed only a few months later. See p. 383 f. below.]

2 [This dream is discussed at greater length in *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 211–13.]

3 [Enclosed in Letter 64 (above), dated Vienna, May 31, 1897.]

4 ['*Impulse*' in the original. '*Impuls*' seems to be used by Freud as a much less common synonym for '*Regung*'. See, for instance, Lecture XXXII of the *New Introductory Lectures* (1933*a*), *GW*, **15**, 105 (*RSE*, **22**, 87), where the two words are apparently used without distinction. It is perhaps unfortunate, however, that both are rendered 'impulse' in this edition. – For a fuller discussion of this issue, see ibid., **24**, 80–1.]

nothing other than a mode of thinking and does not relieve us of the necessity for looking for the motive.[1]

It seems as though this death wish is directed in sons against their father and in daughters against their mother.[2] A maidservant makes a transference [*Übertragung*] from this by wishing her mistress to die so that her master can marry her. (Cf. Lisel's dream about Martha and me.)[3]

Relation between Impulses and Phantasies

Memories appear to bifurcate: one part of them is put aside and replaced by phantasies; another, more accessible part seems to lead directly to impulses. Is it possible that later on impulses can also proceed from phantasies?

Similarly obsessional neurosis and paranoia would proceed *ex aequo* [on equal terms] from hysteria, which would explain the incompatibility between them.[4]

Transposition of Belief

Belief (and doubt) is a phenomenon that belongs wholly to the system of the ego (the *Cs*.) and has no counterpart in the *Ucs*.[5] In the neuroses belief
[256] is displaced; it is denied to the repressed material if it forces its way to reproduction and – as a punishment, one might say – transposed on to the defending material. Titania, who will not love her rightful husband Oberon, is obliged instead to bestow her love on Bottom, the phantasy ass.

Poetry and Fine Frenzy[6]

The mechanism of poetry [*Dichtung*, creative writing] is the same as that of hysterical phantasies. For his *Werther* Goethe combined something he

1 [The mechanism indicated here was elaborated, after a long interval, in 'Mourning and Melancholia' (1916–17*g* [1915]), *RSE*, **14**, 214.]

2 [Perhaps Freud's very first hint at the Oedipus complex, which emerged in full in Letter 71 (p. 291 f. below) some five months later.]

3 [The dream does not seem to have survived. Lisel was the Freuds' nursery governess.]

4 [Cf. Letter 46, p. 258 above.]

5 [What were to become the regular abbreviations, '*Bw*' ('*Bewusst*') and '*Ubw*' ('*Unbewusst*'), are found here for the first time. '*Vbw*' ('*Vorbewusst*', 'preconscious') appears in the accompanying letter (p. 280 above). Freud was using a variety of similar abbreviations at about this time: see Letter 52, p. 261 above. These have been disregarded elsewhere in this translation of the Fliess papers. It will be noticed that all these terms are used here in the 'systematic' sense. Cf. the Editors' Introduction to *The Ego and the Id* (1923*b*), *RSE*, **19**, 5 ff.]

6 [The last two words are in English in the original – taken from Shakespeare's *Midsummer Night's Dream*, Act 5, Scene 1: 'The poet's eye, in fine frenzy rolling . . .'.]

had experienced (his love for Lotte Kästner) and something he had heard (the fate of young Jerusalem who died by his own hand).[1] He was probably toying with the idea of killing himself and found a point of contact in that and identified himself with Jerusalem, to whom he lent a motive from his own love story. By means of this phantasy he protected himself from the consequences of his experience.

So Shakespeare was right in his juxtaposition of poetry and madness (fine frenzy).

Motives for Symptom-formation

Remembering is never a motive but only a way, a method. The first motive for symptom-formation is, chronologically, libido. Thus symptoms, like dreams, are *the fulfilment of a wish*.[2]

At later stages the defence against libido has made room for itself in the *Ucs.* as well. Wish fulfilment must meet the requirements of this unconscious defence. This happens if the symptom is able to operate as a *punishment* (for an evil impulse or from mistrust in the ability to stop oneself).[3] The motives of *libido* and of *wish fulfilment as a punishment* then act by summation. Here the general trend towards abreaction and the irruption of the repressed is unmistakable, and to this the other two motives are added. It appears as though at later stages on the one hand complicated psychical[4] structures [*Gebilde*] (impulses, phantasies, motives) are displaced from the memories, and on the other hand *defence*, arising from the *Pcs.* (the ego), would seem to force its way into the unconscious, so that defence too becomes *multilocular*.

Symptom-formation by identification is linked to phantasies – that is, to their repression in the *Ucs.* – in an analogous way to the alteration of [257]
the ego in paranoia [pp. 254–5 above]. Since the outbreak of *anxiety* is linked to these repressed phantasies, we must conclude that the transformation of libido into anxiety does not occur through defence between the ego and the *Ucs.*, but in the *Ucs.* itself. It follows, therefore, that there is *Ucs.* libido as well.

The repression of impulses seems to produce not *anxiety* but perhaps depression – melancholia. In this way the melancholias are related to obsessional neurosis.

1 [Cf. Draft M, p. 278 above.]

2 [This is already implied in the 'Project' of 1895 (p. 365 below).]

3 [This sentence was mistranscribed in *Anf.* and therefore mistranslated in *SE*.]

4 ['*Psychische*' in the MS. Omitted in *Anf.*, 223.]

Definition of 'Holiness'

'Holiness' is something based on the fact that human beings, for the benefit of the larger community, have sacrificed a portion of their sexual liberty and[1] their liberty to indulge in perversions. The horror of incest (something impious) is based on the fact that, as a result of community of sexual life (even in childhood), the members of a family hold together permanently and become incapable of contact with strangers. Thus incest is antisocial – civilization consists in this progressive renunciation. Contrariwise the 'superman'.[2]

LETTER 66[3]

. . . I still do not know what has been happening in me. Something from the deepest depths of my own neurosis has ranged itself against any advance in an understanding of the neuroses and you have somehow been involved in it. For my writing paralysis seems to me designed to hinder our communications. I have no guarantees of this; they are only feelings of a highly obscure nature. Has nothing of the kind happened to you?
[258] For the last few days it has seemed to me that an emergence from this obscurity is in preparation. I notice that in the meantime I have made all kinds of advances in my work, and every now and then an idea has once more occurred to me. The hot weather and overwork have no doubt had their share in this.

Well then, I see that defence against the memories does not prevent their giving rise to higher psychical structures, which persist for a while and are then themselves subjected to defence. This, however, is of a most highly specific kind – precisely as in dreams, which contain *in nuce* [in a nutshell] the psychology of the neuroses quite generally. What we are faced with are falsifications of memory and phantasies – these latter relating to the past or future. I know roughly the rules in accordance with which these structures are put together and the reasons why they are stronger than genuine memories, and I have thus learnt fresh things to help in characterizing the processes in the *Ucs*. Alongside of these,

1 [Omitted in *Anf*., 223.]

2 [This paragraph contains the germ of much of Freud's later writings on sociology. See, for instance, '"Civilized" Sexual Morality' (1908*d*), *RSE*, **9**, 163 f., and Chapter VII of *Civilization and its Discontents* (1930*a*), ibid., **21**. Some comments on the word '*heilig*' can be found in an Editors' footnote to the third essay, Part II (D), of *Moses and Monotheism* (1939*a*), ibid., **23**, 109 n. 1.]

3 [Dated Vienna, July 7, 1897. – This and the next few letters may seem at first sight to be too personal for inclusion here. But, on the contrary, they are of central interest for the history of Freud's scientific ideas, for they relate to his own self-analysis which, like Galileo's telescope, opened the way to a new chapter in human knowledge.]

perverse impulses arise, and when, as becomes necessary later, these phantasies and impulses are repressed, the higher determinations of the symptoms already following from the memories make their appearance, and fresh motives for retaining the illness. I am learning a few typical cases of the putting together of these phantasies and impulses and a few typical determinants for the emergence of repression against them. This knowledge is not yet complete. My technique is beginning to prefer a particular method as being the natural one.

The most assured thing seems to me to be the explanation of dreams, but it is surrounded by a vast number of obstinate riddles. The organological questions await your solution: I have made no advances there.

There is an interesting dream of wandering about among strangers, totally or half undressed and with feelings of shame and anxiety. Oddly enough, it is the rule that the people do *not* notice it – for which we have to thank wish fulfilment. This dream material, which goes back to exhibiting in childhood, has been misunderstood and worked over didactically in a well-known fairy tale. (The king's imaginary clothes – 'Talisman'.)[1] The ego habitually misinterprets other dreams in the same way.[2]

. . . . . .

LETTER 67[3]

. . . Things are fermenting in me, but I have finished nothing. I am well [259]
satisfied with the psychology. I am tormented with grave doubts about my theory of the neuroses. I am very sluggish in my mind and have not succeeded here in calming the agitation in my head and feelings; that can only happen in Italy.

After having been very cheerful here, I am now enjoying a period of ill-temper. The chief patient I am concerned with is myself. My mild hysteria (very much aggravated by work, however) has been resolved one piece further: but the rest is still at a standstill. It is on that that my mood mainly depends. The analysis is more difficult than any other. It, too, is what paralyses my psychical strength for describing and

1 [The reference is, of course, to Hans Andersen's *The Emperor's New Clothes*. *Der Talisman* is a dramatized version of it in verse by the German playwright Ludwig Fulda (1862–1939). – The whole subject is dealt with at length in Chapter V (D) of *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 215 ff.]

2 [On this, cf. *The Interpretation of Dreams*, ibid., **5**, 438 f. and 448.]

3 [Dated Aussee, August 14, 1897.]

communicating what I have achieved so far. But I think it must be done, and is a necessary intermediate stage in my work.

. . . . . .

LETTER 69[1]

. . . I will confide in you at once the great secret that has been slowly dawning on me in the last few months. I no longer believe in my *neurotica* [theory of the neuroses]. This is probably not intelligible without an explanation; after all, you yourself found what I could tell you credible. So I will begin historically from the question of the origin of my reasons for disbelief. The continual disappointments in my attempts at bringing an[2] analysis to a real conclusion, the running away of people who had for a time seemed most in my grasp, the absence of the complete successes on which I had reckoned, the possibility of explaining the partial successes in other ways, on ordinary lines – this was the first group. Then came surprise at the fact that in every case the *father*, not excluding my own,[3] had to be blamed as a pervert – the realization of the unexpected frequency of hysteria, in which the same determinant is invariably established, though such a widespread extent of perversity towards children is, after all, not very probable. (The perversity would have to be immeasurably more frequent than the hysteria, since the illness only arises where there has been an accumulation of events and
[260] where a factor that weakens defence has supervened.) Then, thirdly, the certain insight that there are no indications of reality[4] in the unconscious, so that one cannot distinguish between the truth and fiction that is cathected with affect. (Thus, the possibility remained open that sexual phantasy invariably seizes upon the theme of the parents.) Fourthly, the reflection that in the most deep-going psychosis the unconscious memory does not break through, so that the secret of the childhood experiences is not betrayed even in the most confused delirium. If in this way we see that the unconscious never overcomes the resistance of the conscious, then, too, we lose our expectation that in treatment the opposite will happen, to the extent of the unconscious being completely tamed[5] by the conscious.

1 [Dated Vienna, September 21, 1897.]

2 [This word was misread in *Anf.* and *SE*; it is '*eine*' ('an') not '*meine*' ('my').]

3 ['*Mein eigener nicht ausgeschlossen*', omitted in *Anf.*, 230.]

4 [For this term, see Part I, Section 15 of the 'Project', p. 350 below.]

5 [Cf. the 'Project', p. 406 *n.* 1 below.]

Envelope of Freud's letter to Fliess dated September 21, 1897

Envelope of Freud's letter to Fliess dated September 21, 1897

The envelope was addressed simply to: 'Herrn Dr Wilh. Fliess, v.d. Heydtstrasse Berlin.' It contained the letter in which Freud confided to his friend that he no longer believed in his own theory of the traumatic aetiology of the neuroses.

By permission of The Marsh Agency Ltd., on behalf of Sigmund Freud Copyrights.

I was influenced so far by this that I was prepared to give up two things: the complete resolution of a neurosis and the certain knowledge of its aetiology in childhood. I have no idea now where I have got to, since I have not achieved a theoretical understanding of repression and its interplay of forces. It seems to have become once again arguable that it is only later experiences that give the impetus to phantasies, which then hark back to childhood; and with this the factor of a hereditary disposition regains a sphere of influence from which I had made it my task to expel it – in the interest of throwing a flood of light on neurosis.

If I were depressed, confused, or exhausted, doubts of this kind would no doubt have to be interpreted as signs of weakness. Since I am in an opposite state, I must recognize them as the result of honest and valid intellectual work and must be proud that after going so deep I am still capable of such criticism. Can it be that this doubt merely represents an episode in advance towards further knowledge?

It is remarkable, too, that there has been an absence of any feeling of shame, for which, after all, there might be occasion. Certainly I shall not tell it in Dan or speak of it in Askelon, in the land of the Philistines.[1] But in your eyes and my own I have more of the feeling of a victory than of a defeat – and, after all, that is not right.[2]

. . . . . .

1 [Freud is misquoting II *Samuel* i, 20: 'Tell it not in Gath, publish it not in the streets of Askelon; lest the daughters of the Philistines rejoice, lest the daughters of the uncircumcised triumph.']

2 [This letter announces for the first time (apart from a hint in Letter 67, p. 285 above) Freud's doubts about his theory of the traumatic aetiology of the neuroses, which he had held for at least the previous five years (see his letter to Breuer of June 29, 1892, p. 175 f. above). In one of his later accounts of his discovery of the mistake (in his *Autobiographical Study* (1925*d*), *RSE*, **20**, 29) he remarks that the error 'might well have had fatal consequences for the whole of my work'. It was not for another eight years that he did in fact publish the facts in the streets of Askelon – in the second of the *Three Essays* (1905*d*), ibid., **7**, 169 – although he had already communicated his changed views to Löwenfeld by 1903, who published them in 1904 (see also Freud, 1904*f*; *RSE*, **7**, 233 ff.; Masson, 1984, 119–22). This delay may possibly be explained in part by a continuation of Freud's own doubts on the subject. It seems, at all events, that for some months after writing this letter he was far from having completely abandoned the traumatic theory. See the letter of November 14, 1897, p. 294 ff. (Letter 75) below and the letter of March 10, 1898, p. 300 (Letter 84) below, as well as the discussion of the psychoneuroses in 'Sexuality in the Aetiology of the Neuroses' (1898*a*), *RSE*, **3**, 275. His uncertainty was probably only laid to rest with the full discovery of the dynamic nature of the sexual drive impulses present in infancy, and the full realization that phantasies can operate with all the force of real experiences. A full account of the whole subject is given in an Editors' footnote to Lecture XXXIII of the *New Introductory Lectures*, ibid., **22**, 106–7 *n*. In the passage to which the footnote is attached, Freud returns to the traumatic aetiology, but in a very much modified form.]

LETTER 70[1]

[261] . . . [October 3] Very little is still happening to me externally, but internally something most interesting. For the last four days my self-analysis, which I consider indispensable for throwing light upon the whole problem, has proceeded in dreams and has presented me with the most valuable inferences and clues. At some points I have a feeling of being at the end, and so far, too, I have always known where the dream of the next night would take things up. To describe it in writing is more difficult than anything else, and also it would be far too diffuse. I can only say shortly that *der Alte* [my father] played no active part in my case, but that no doubt I drew an inference by analogy from myself on to him; that the 'prime originator' [of my troubles] was a woman, ugly, elderly, but clever, who told me a great deal about God Almighty and Hell and who gave me a high opinion of my own capacities;[2] that later (between the ages of two [262] and two and a half) my libido was stirred up towards *matrem*, namely on the occasion of a journey with her from Leipzig to Vienna, during which we must have spent the night together and I must have had an opportunity of seeing her *nudam*[3] – you drew the conclusion from this long ago for your own son, as a remark of yours revealed to me –; that I greeted my brother (who was a year my junior and died after a few months) with ill-wishes and genuine childish jealousy, and that his death left the germ of self-reproaches in me. I have also long known the companion in my evil deeds between the ages of one and two. It was my nephew, a year older than myself, who is now living in Manchester and who visited us in Vienna when I was fourteen. The two of us seem occasionally to have behaved in a cruel fashion to my niece, who was a year younger. This nephew and this younger brother have determined what is neurotic, but also what is intense, in all my friendships.[4] You yourself have seen my travel anxiety in full swing.

I have not yet found out anything about the scenes which underlie the

1 [Dated Vienna, October 3 and 4, 1897.]

2 [This old nurse is referred to in *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 220, and in *The Psychopathology of Everyday Life* (1901*b*), ibid., **6**, 44–5. But these do not include the account of Freud's reconstruction of her behaviour from his dreams and its verification, which only appears here. Sajner (1968) and Gicklhorn (1969) identify the nurse as Monika Zajic (but see also Sajner, 1981). It seems she was only 'elderly' from the viewpoint of a child, as she was premenopausal (see below).]

3 [Freud seems in fact to have been four years old at the time of this journey: see Jones (1953, 14).]

4 [Freud's relations with his nephew John and his niece Pauline are further explained and discussed in *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 175 and 205, and **5**, 378–9 and 431–5, and in the disguised autobiographical episode in 'Screen Memories' (1899*a*), ibid., **3**, 300 ff.]

whole business. If they come to light and if I succeed in resolving my own hysteria, I shall be grateful to the memory of the old woman who provided me at such an early age with the means for living and going on living. As you see, my old liking for her is breaking through again. I can give you no idea of the intellectual beauty of the work. . . .

. . . [October 4] Today's dream has produced what follows, under the strangest disguises.

She was my teacher in sexual matters and scolded me for being clumsy and not being able to do anything. (This is always how neurotic impotence comes about; it is thus that fear of incapacity at school obtains its sexual substratum.) At the same time I saw the skull of a small animal and in the dream I thought 'Pig!' But in the analysis I associated it with your wish two years ago that I might find a skull on the Lido to enlighten me, as Goethe once did. But I failed to find one. So I was a little fool.[1] The whole dream was full of the most mortifying allusions to my present [263]
powerlessness as a therapist. Perhaps this is where an inclination to believe that hysteria is incurable has its start. Besides this, she washed me in reddish water, in which she had previously washed herself. (The interpretation is not difficult; I find nothing like this in the chain of my memories, so I regard it as a genuine ancient discovery.) And she made me carry off '*zehners*' (ten kreuzer pieces)[2] and give them to her. There is a long chain from these first silver *zehners* to the heap of paper ten-florin notes which I saw in the dream as Martha's housekeeping money. The dream can be summed up as 'bad treatment'. Just as the old woman got money from me for her bad treatment of me, so today I get money for my bad treatment of my patients. A special part was played by Frau Qu., whose remark you reported to me: I ought not to take anything from her as she was the wife of a colleague. (Of course he made it a condition that I should.)

A severe critic might say of all this that it was retrogressively phantasied and not progressively determined. *Experimenta crucis* [crucial experiments] would have to decide against him. The reddish water seems to be one such already. Where do all patients get the frightful perverse details which are often as remote from their experience as from their knowledge?

1 ['*Ein kleiner Schafskopf*', literally 'a little sheep's head'. – The reference is to the story that Goethe found the skull of a sheep on the Lido at Venice, which gave him the idea of the so-called 'vertebral' theory of the skull. This story makes its appearance again in *On Dreams* (1901*a*) as an association to another dream (*RSE*, **5**, 599).]

2 [Silver coins of little value.]

LETTER 71[1]

. . . My self-analysis is in fact the most essential thing I have at present and it promises to become of the greatest value to me if it reaches its end. In the middle of it, it suddenly ceased for three days and I had the feeling of being tied up inside which patients complain of so much, and I was really inconsolable. . . .

It is an uncanny fact that my practice still allows me a great deal of time.

The whole thing is all the more valuable for my purposes since I have succeeded in finding a few real points of reference for the story. I asked my mother whether she still recollected the nurse. 'Of course,' she said, 'an elderly person, very clever. She was always taking you to church: when you came back afterwards you used to preach sermons and tell us all about God Almighty. During my confinement when Anna was born,' (she is two and a half years my junior) 'it was discovered that she was a
[264] thief, and all the shiny new kreuzers and zehners and all the toys that had been given to you were found in her possession. Your brother Philipp [see below] himself went for the policeman and she was given ten months in prison.' Now just see how this confirms the conclusions of my dream interpretation. I have found a simple explanation of my own possible mistake. I wrote to you that she led me into stealing zehners and giving them to her. The dream really meant that she stole them herself. For the dream picture was a memory of my taking money from the mother of a doctor – that is, wrongfully. The correct interpretation is: I = she, and the mother of the doctor equals my mother. So far was I from knowing that she was a thief that I made a wrong interpretation.

I also made enquiries about the doctor we had in Freiberg, because a dream showed a great deal of resentment against him. In the analysis of the figure in the dream behind which he was concealed I thought also of a Professor von Kraus, who was my history master at school. He did not seem to fit in at all, as my relations with him were indifferent, or, rather, agreeable. My mother then told me that the doctor in my childhood had only one eye, and of all my schoolmasters Professor Kraus too was the only one with that same defect.[2]

1 [Dated Vienna, October 15, 1897.]

2 [The episode of the one-eyed doctor is mentioned in *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 15, and in Lecture XIII of the *Introductory Lectures* (1916–17*a*), ibid., **15**, 175. – Sajner (1968) identifies the doctor, who was also the mayor of Freiburg, as Dr Josef Pur. The schoolmaster was Victor von Kraus (regarding whom, see Knöpfmacher, 1979).]

The evidential value of these coincidences might be invalidated by the objection that on some occasion in my later childhood I had heard that the nurse was a thief, and that I had then apparently forgotten it till it finally emerged in the dream. I think myself that that is so. But I have another unexceptionable and amusing piece of evidence. I said to myself that, if the old woman disappeared so suddenly, it must be possible to point to the impression this made on me. Where is that impression, then? A scene then occurred to me which, for the last 25 years,[1] has occasionally emerged in my conscious memory without my understanding it. My mother was nowhere to be found: I was screaming my head off. My brother Philipp, twenty years older than me, was holding open a cupboard [*Kasten*] for me, and, when I found that my mother was not inside it either, I began crying still more, till, looking slim and beautiful, she came in by the door. What can this mean? Why was my brother opening the cupboard, though he knew that my mother was not in it, so that this could not pacify me? And then suddenly I understood. I had asked him to do it. When I missed my mother, I had been afraid she had vanished from me just as the old woman had a short time before. Now I must have heard that the old woman had been locked up and consequently I [265]
must have thought that my mother had been too – or rather had been 'boxed up' ['*eingekastelt*'];[2] for my brother Philipp, who is 63 now, is fond to this very day of talking in this punning fashion. The fact that it was to him in particular that I turned proves that I knew quite well of his share in the nurse's disappearance.[3]

Since then I have got much further, but have not yet reached any real stopping point. Communicating what is unfinished is so diffuse and laborious that I hope you will excuse me from it and content yourself with a knowledge of the portions that are established with certainty. If the analysis contains what I expect from it, I will work it over systematically and put it before you afterwards. So far I have found nothing completely new, only complications, to which I am ordinarily[4] accustomed. It is not quite easy. To be completely honest with oneself is good practice. One single thought of general value has been revealed to me. I have found, in my own case too, falling in love with the mother and jealousy of the

1 [Misread as 29 years in *Anf.* and *SE*.]

2 [Literally 'put in a *Kasten* (or cupboard)'.]

3 [The story of the screen memory about the cupboard was included at greater length in Chapter IV of *The Psychopathology of Everyday Life* (1901*b*), *RSE*, **6**, 43–5. In a footnote added to that passage in 1924 Freud pointed out the womb symbolism of the cupboard, and pursued the whole analysis further (ibid., 45 *n*. 2).]

4 ['*Sonst*' in the MS. '*Bis jetzt*' ('hitherto') in *Anf.*, 237.]

father, and I now regard it as a universal event of early childhood, even if not so early as in children who have been made hysterical. (Similarly with the romance of parentage in paranoia – heroes, founders of religions.)[1] If that is so, we can understand the riveting power of *Oedipus Rex*, in spite of all the objections raised by reason against its presupposition of destiny; and we can understand why the later 'dramas of destiny' [*Schicksalsdrama*][T] were bound to fail so miserably. Our feelings rise against any arbitrary, individual compulsion [of fate], such as is presupposed in [Grillparzer's] *Die Ahnfrau*, etc. But the Greek legend seizes on a compulsion which everyone recognizes because he feels its existence within himself. Each member of the audience was once, in germ and in phantasy, just such an Oedipus, and each one recoils in horror from the dream fulfilment here transplanted into reality, with the whole quota of repression which separates his infantile state from his present one.

Schicksal

A fleeting idea has passed through my head of whether the same thing may not lie at the bottom of *Hamlet* as well. I am not thinking of Shakespeare's conscious intention, but I believe rather that here some real event instigated the poet to his representation, in that the unconscious in him understood the unconscious in his hero. How can Hamlet the hysteric justify his words 'Thus conscience does make cowards of us all', how can he explain his hesitation in avenging his father by the murder of his uncle – he, the same man who sends his courtiers to their death without a scruple and who is positively precipitate in killing Laertes?[2] How better could he justify himself than by the torment he suffers from the obscure memory that he himself had meditated the same deed against his father from passion for his mother, and – 'use every man after his desert, and who should 'scape whipping?' His conscience is his unconscious sense of guilt [*unbewusstes Schuldbewusstsein*]. And is not his sexual alienation [pp. 221–2 above] in his conversation with Ophelia typically hysterical? And his rejection of the instinct [*Instinkt*][T] which seeks to beget children? And, finally, his transferring [*Übertragung*] the deed from his own father to Ophelia's? And does he not in the end, in the same remarkable way as my hysterical patients, bring down punishment on himself by suffering the same fate as his father of being poisoned by the same rival?[3]

[266]

. . . . . .

1 [See pp. 271 and 280 above.]

2 [Hamlet actually killed Polonius, not his son Laertes.]

3 [This is the first explicit introduction of the Oedipus complex, hinted at above on p. 282. Its first published appearance was in *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 231–6. The application of the idea to *Oedipus Rex* and to *Hamlet* is to be found in the same passage.]

LETTER 72[1]

. . . An idea about resistance has enabled me to put straight all those cases of mine which had run into fairly severe difficulties, and to start them off again satisfactorily. Resistance, which finally brings work to a halt, is nothing other than the child's past character, his degenerate character, which (as a result of those experiences which one finds present consciously in what are called degenerate cases) has developed or might have developed, but which is overlaid here by the emergence of repression. I dig it out by my work, it struggles; and what was to begin with such an excellent, honest fellow becomes low, untruthful or defiant, and a malingerer – till I tell him so and thus make it possible to overcome this character. In this way resistance has become something actual and tangible to me, and I wish, too, that, instead of the concept of repression, [267]
I already had what lies concealed behind it.[2]

This infantile character develops during the period of 'longing', after the child has been withdrawn from the sexual experiences. Longing is the main character trait of hysteria, just as a current anaesthesia (even though only potential) is its main symptom. During this same period of longing the phantasies are constructed and (invariably?) masturbation is practised, which afterwards yields to repression. If it does not give way, then there is no hysteria; the discharge of sexual excitation removes the possibility of hysteria for the most part. It has become clear to me that various obsessional movements [*Zwangsbewegungen*] have the meaning of a substitute for the abandoned movements of masturbation. . . .

. . . . . .

LETTER 73[3]

. . . My analysis proceeds and remains my chief interest. Everything is still obscure, even the problems; but there is a comfortable feeling that one has only to rummage in one's own store-room to find, sooner or later, what one needs. The most disagreeable thing are the moods, which often completely hide reality from one. For someone like me, too, sexual excitation is no longer of use. But I am still cheerful with it all. As regards results, just now there is once more a lull.

1 [Dated Vienna, October 27, 1897.]

2 [This refers to the organic foundations of repression. See Letter 75, p. 294 f. below.]

3 [Dated Vienna, October 31, 1897.]

Do you think that children's speeches in their sleep count as dreams? If so, I can present you with the very youngest of wishful dreams: Little Anna, aged one and a half. She had to starve one day at Aussee because she was sick in the morning, which was put down to a meal of strawberries. During the following night she called out a whole menu in her sleep: 'Stwawbewwies, wild stwawbewwies, omblet, pudden!' I may have told you this already.[1]

. . . . . .

LETTER 75[2]

[268] . . . 'It was on November 12, 1897. The sun was in the eastern quarter; Mercury and Venus were in conjunction –' No, announcements of births no longer start like that. It was on November 12, a day dominated by a left-sided migraine, on which afternoon Martin sat down to write a new poem,[3] on which evening Oli lost his second tooth,[4] that, after the frightful labour pains of the last few weeks, I gave birth to a new piece of knowledge. Not entirely new, to tell the truth; it had repeatedly shown itself and withdrawn again;[5] but this time it stayed, and looked upon the light of day. Funnily enough, I have a presentiment of such events a good while beforehand. For instance, I wrote to you once in the summer [Letter 64, p. 280 above] that I was going to find the source of normal sexual repression (morality, shame, etc.) and then for a long time failed to find it. Before the holidays [Letter 67, p. 285] I told you that the most important patient for me was myself; and then suddenly, after I came back from the holidays, my self-analysis, of which there was then no sign,[6] started ahead. A few weeks ago [Letter 72, p. 293] came my wish that repression might be replaced by the essential thing lying behind it; and that is what I am concerned with now.

I have often suspected that something organic played a part in repression; I was able once before to tell you that it was a question of the

1 [This is repeated in *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 116, in *On Dreams* (1901*a*), ibid., **5**, 582 f., and in Lecture VIII of the *Introductory Lectures* (1916–17*a*), ibid., **15**, 115.]

2 [Dated Vienna, November 14, 1897.]

3 I was not supposed to know this. It seems that his poetic tonsils have been cut. [This and the following two notes are Freud's own.]

4 The first one was in fact pulled out on the evening of November 9 by the nurse; it might perhaps have lasted till the 10th. [Martin and Oliver were Freud's eldest and second sons.]

5 Only tall fellows for Sa Majesté le Roi de Prusse. [The earlier suggestions were rejected as inferior. The Potsdam Guard under Frederick William I (Frederick the Great's father) was recruited wholly from giants.]

6 [Not strictly correct. See, for instance, Letter 67, of August 14, p. 285 above.]

abandonment of former sexual zones [pp. 265–6 and 268 above] and I was able to add that I had been pleased at coming across a similar idea in Moll.[1] *Privatim* [privately] I concede priority in the idea to no-one; in my case the notion was linked to the changed part played by sensations of smell: upright carriage adopted, nose raised from the ground, at the same time a number of formerly interesting sensations attached to the earth becoming repulsive – by a process still unknown to me. (He turns [269]
up his nose = he regards himself as something peculiarly noble.) Now, the zones which no longer produce a release of sexuality in normal and mature human beings must be the regions of the anus and of the mouth and throat. This is to be understood in two ways: first, that the appearance and idea of these zones no longer produce an exciting effect, and second, that the internal sensations arising from them furnish no contribution to the libido, in the way in which the sexual organs proper do. In animals these sexual zones continue in force in both respects; if this persists in human beings too, perversion results. We must assume that in infancy the release of sexuality is not yet so much localized as it is later, so that the zones which are later abandoned (and perhaps the whole surface of the body as well) also instigate something that is analogous to the later release of sexuality. The extinction of these initial sexual zones would have a counterpart in the atrophy of certain internal organs in the course of development. A release of sexuality – as you know, I have in mind a kind of secretion which is rightly felt as the internal state of the libido – comes about, then, not only (1) through a peripheral stimulus upon the sexual organs, or (2) through the internal excitations arising from those organs, but also (3) from ideas – that is, from memory traces – therefore also[2] by the path of deferred action [*Nachträglichkeit*].[3] (You are already familiar with this line of thought.) If a child's genitals have been irritated by someone, years afterwards the memory of this will produce by deferred action a release of sexuality far stronger than at the time, because the determining apparatus and the quota of secretion have increased in the meantime. Thus a non-neurotic deferred action may occur normally, and this generates compulsion. (Our other memories operate ordinarily only because they have operated as experiences.) Deferred action of this kind occurs as well in connection with memories of excitations of the *abandoned* sexual zones. The outcome, however, is

1 [Albert Moll (1862–1939), neurologist in Berlin. – The reference is to Moll (1897–8), **2**, 376 (cf. Sulloway, 1979).]

2 ['*Auch*' in the MS. Omitted in *Anf.*, 247.]

3 [The word recurs four times in this paragraph.]

not a release of libido but of an unpleasure, an internal situation which is analogous to disgust in the case of an object.

To put it crudely, the current memory stinks just as an actual object stinks; and just as we turn away our sense organ (the head and nose) in disgust, so do our preconsciousness and our conscious sense turn away from the memory. This is *repression*.

What, now, does normal repression furnish us with? Something which, free, can lead to anxiety, if psychically bound, to rejection – that is to say, the affective basis for a multitude of intellectual processes of development, such as morality, shame, etc. Thus the whole of this arises at the
[270] expense of extinct (potential) sexuality. From this we can see that, with the successive waves of a child's development, he is overlaid with piety, shame, and such things, and how the non-occurrence of this extinction of the sexual zones can produce moral insanity[1] as a developmental inhibition. These successive waves of development probably have a different chronological arrangement in the male and female sexes. (Disgust appears earlier in little girls than in boys.) But the main distinction between the sexes emerges at the time of puberty, when girls are seized upon by a *non*-neurotic *sexual* repugnance and males by libido. For at that period a further sexual zone is (wholly or in part) extinguished in females which persists in males. I am thinking of the male genital zone, the region of the clitoris, in which during childhood sexual sensitivity is shown to be concentrated in girls as well as boys. Hence the flood of shame which overwhelms the female at that period, till the new, vaginal zone is awakened, whether spontaneously or by reflex action. Hence too, perhaps, the anaesthesia of women, the part played by masturbation in children predisposed to hysteria and the discontinuance of masturbation if hysteria results.

And now for the neuroses. Experiences in childhood which merely affect the genitals never produce neurosis in males (or masculine females) but only compulsive masturbation and libido. But since as a rule experiences in childhood have also affected the two other sexual zones, the possibility remains open for males also that libido awakening through deferred action [*Nachträglichkeit*] may lead to repression and to neurosis. Insofar as memory has lighted upon an experience connected with the genitals, what it produces by deferred action [*nachträglich*] is libido. Insofar as [it has lighted upon an experience connected with] the anus, mouth, etc., it produces deferred [*nachträglichen*] *internal disgust*, and the final outcome is consequently that a quota of libido is not able, as is

1 [These two words are in English in the original.]

ordinarily the case, to force its way through to action or to translation [*Übersetzung*] into psychical terms [p. 219 f. above], but is obliged to proceed in a *regressive* direction (as happens in dreams). Libido and disgust would seem to be associatively linked. We owe it to the former that the memory cannot lead to general unpleasure, etc., but that it finds a psychical use; and we owe it to the latter that this use furnishes nothing but symptoms instead of purposive ideas. In that case, it ought not to be hard to grasp the psychological side of this; the organic factor in it is whether the surrender of the sexual zones takes place according to the masculine or feminine type of development or whether it takes place at all.

It is probable, then, that the choice of neurosis (the decision whether [271] hysteria or obsessional neurosis or paranoia emerges) depends on the nature of the wave of development (that is to say, its chronological placing) which enables repression to occur – i.e. which transforms a source of internal pleasure into one of internal disgust.[1]

This is where I have got to so far – with all the obscurities involved. I have decided, then, henceforth to regard as separate factors what causes libido and what causes anxiety. I have also given up the idea of explaining libido as the masculine factor and repression as the feminine one. [Cf. p. 278 above.] These are, in any case, important decisions. The obscurity lies mainly in the nature of the change by which the internal sensation of need becomes the sensation of disgust. I need not draw your attention to other obscure points. The main value of the synthesis lies in its linking together the neurotic process and the normal one. There is now a crying need, therefore, for a prompt elucidation of common neurasthenic anxiety.

My self-analysis is still interrupted and I have realized the reason. I can only analyse myself with the help of knowledge obtained objectively (like an outsider). Genuine self-analysis is impossible; otherwise there would be no [neurotic] illness. Since I still find some puzzles in my patients, they are bound to hold me up in my self-analysis as well.[2]

1 [This is an early emergence of the problem of 'the reversal of affect under repression', already touched upon on pp. 249–50 and 262 above, which crops up again and again in Freud's writings. See, for instance, the 'Dora' case history (1905*e*), where a number of references can be found, *RSE*, **7**, 26–7, and the solution offered in *Inhibitions, Symptoms and Anxiety* (1926*d*), ibid., **20**, 81–2.]

2 [This letter evidently contains a number of remarkable anticipations of Freud's later views. (1) The connection between repression and the adoption of an upright stance, already hinted at in Letter 55, p. 268 above, appears in the 'Rat Man' analysis (1909*d*), *RSE*, **10**, 187–8, in the second contribution to the psychology of love (1912*d*), ibid., **11**, 176, and in two long footnotes to Chapter IV of *Civilization and its Discontents* (1930*a*), ibid., **21**, 90–1 *n.* and 95–6 *n.* 3, where the concept of 'organic repression' is discussed at length. (2) Erotogenic zones had been spoken of earlier (Letter 52, p. 266 above), but the idea of a succession of such zones in childhood, and of a later

LETTER 79[1]

[272] . . . It has dawned on me that masturbation is the one major habit, the 'primal addiction' and that it is only as a substitute and replacement for it that the other addictions – for alcohol, morphine, tobacco, etc. – come into existence.[2] The part played by this addiction in hysteria is quite enormous; and it is perhaps there that my great, still outstanding, obstacle is to be found, wholly or in part. And here, of course, the doubt arises of whether an addiction of this kind is curable, or whether analysis and therapy are brought to a stop at this point and must content themselves with transforming a case of hysteria into one of neurasthenia.[3]

As regards obsessional neurosis the fact is confirmed that the locality at which the repressed breaks through is the *word presentation* [*Wortvorstellung*] and not the concept [*Begriff*] attached to it. (More precisely, the word *memory* [*Wort-Erinnerung*].) Hence the most disparate things are readily united as an obsessional idea under a single word with more than one meaning. The trend towards breaking through makes use of an ambiguous word of this kind [with its several meanings] as though it were killing several flies at a blow.[4] Take, for instance, the following case. A girl who was attending a school of needlework and was near the end of her course was plagued by this obsessional idea: 'No, you mustn't go off, you haven't *finished* yet, you must *make* [*machen*] some more, you must learn a lot more.' Behind this lay a memory of childhood scenes in which she was put on the pot but wanted to get away and was subjected to the same compulsion:[5] 'You mustn't go off, you haven't *finished* yet, you must *do* [*machen*] some more.' The word '*machen*' [meaning both 'make' and

reaction against them, and in particular the insistence on the changeover in girls from clitoridal to vaginal sexuality – much of this was only fully exploited in the *Three Essays on the Theory of Sexuality* (1905*d*), *RSE*, **7**, 194–6. (3) The same is true of the part attributed here to regression in the formation of neuroses. On the other hand, the criticism of the traumatic theory expressed in Letter 69 seems largely forgotten in the present letter. (See Editors' footnote, p. 287 *n.* 2 above.) (4) The final paragraph, dealing with the possibility of self-analysis, raised technical problems for future solution. A long account of Freud's views on this can be found in an Editors' footnote to his history of the psychoanalytic movement (1914*d*), *RSE*, **14**, 17 *n.* 1.]

1 [Dated Vienna, December 22, 1897.]

2 [This idea is touched on in Letter 55 (p. 267 above) and in a paper published very soon after this, 'Sexuality in the Aetiology of the Neuroses' (1898*a*), *RSE*, **3**, 270; but thereafter it reappears only after a very long interval, in connection with Dostoevsky's addiction to gambling (1928*b*), ibid., **21**, 179–80.]

3 [For Freud's later discussions on masturbation, see an Editors' footnote to Draft B, p. 208 *n.* 3 above.]

4 [The Grimm fairy tale of 'The Little Tailor and Seven at a Blow'.]

5 [The parallelism between this (external) compulsion [*Zwang*] and the later (internal) one [*Zwangsvorstellung* = 'obsessional idea'] is lost in translation.]

'do'] made it possible to bring together the later situation and the infantile one. Obsessional ideas are often clothed in a remarkable *verbal vagueness* in order to permit of this multiple employment. If we take a closer (conscious) look at this example, we find alongside of it the expression 'You must learn more', which later became the fixed obsessional idea, and arose through a mistaken interpretation of this kind on the part of the conscious.[1] [273]

This is not entirely arbitrary. The word '*machen*' has itself passed through an analogous transformation in its meaning. An old phantasy of mine, which I should like to recommend to your linguistic penetration, deals with the derivation of our verbs from originally copro-erotic terms like this.

I can scarcely enumerate for you all the things that I (a modern Midas)[2] turn into – excrement. This fits in perfectly with the theory of internal stinking [pp. 295–6 above]. Above all, money itself. I think the association is through the word 'dirty' as a synonym for 'miserly'. In the same way everything to do with birth, miscarriage, menstruation, goes back to the lavatory via the word '*Abort*' ['lavatory'] ('*Abortus*') ['abortion']. This is quite crazy, but it is entirely analogous to the process by which words take on a transferred meaning as soon as new concepts appear which call for denotation. . . .

Have you ever seen a foreign newspaper which has passed the Russian censorship at the frontier? Words, whole clauses and sentences are blacked out so that what is left becomes unintelligible. A *Russian censorship* of this kind comes about in psychoses and produces the apparently meaningless deliria.[3]

. . . . . .

1 [Much of this is included in the 'Rat Man' case history (1909*d*). See, in particular, *RSE*, **10**, 169–70.]

2 [Whose touch turned everything into gold.]

3 [The analogy of the censorship, which was to become so prominent later, especially in *The Interpretation of Dreams*, had already been used by Freud in *Studies on Hysteria* (1895*d*), ibid., **2**, 239 f. and 251, and the second paper on the neuropsychoses of defence (1896*b*), ibid., **3**, 190–1 and 192. – An extended version of these last sentences (including the Russian analogy) can be found in *The Interpretation of Dreams*, ibid., **5**, 473. The meaning of the German term '*Delirien*' is ambiguous. As with the French '*délire*', the word is often applied in psychiatry to delusions or hallucinations. 'Hysterical deliria' occur frequently in Freud's writings at this period. See, in particular, the case history of Frau Emmy von N. in *Studies on Hysteria* (1895*d*), ibid., **2**. In the 'Rat Man' analysis (1909*d*), Freud uses the term 'delirium' in a special sense, which he explains at some length (ibid., **10**, 126 and 168–9).]

LETTER 84[1]

[274] . . . It was no small feat on your part to see the dream book lying finished before you.[2] It has come to a halt again and meanwhile the problem has deepened and widened. It seems to me as though the theory of wish fulfilment has brought only the psychological solution and not the biological, or, rather, metapsychical one. (I am going to ask you seriously, by the way, whether I may use the name of metapsychology for my psychology that leads behind consciousness.)[3] Biologically, dream life seems to me to derive entirely from the residues of the prehistoric period of life (between the ages of one and three) – the same period which is the source of the unconscious and alone contains the aetiology of all the psychoneuroses, the period normally characterized by an amnesia analogous to hysterical amnesia. This formula suggests itself to me: What is *seen* in the prehistoric period produces *dreams*; what is *heard* in it produces *phantasies*; what is *experienced sexually* in it produces the psychoneuroses.[4] The repetition of what was experienced in that period is in itself the fulfilment of a wish; a recent wish only leads to a dream if it can put itself in connection with material from this prehistoric period, if the recent wish is a derivative of a prehistoric one or can get itself adopted by one. It is still an open question how far I shall be able to adhere to this extreme theory and how far I can expose it to view in the dream book.[5]

. . . . . .

1 [Dated Vienna, March 10, 1898.]

2 [This was a phantasy of Fliess's contained in a letter to which this was Freud's reply. Freud was now chiefly engaged on *The Interpretation of Dreams* (1900*a*), in which Fliess's letter is mentioned (*RSE*, **4**, 152) as an association to the dream of the 'botanical monograph'.]

3 [Freud had already used the word in a letter to Fliess two years earlier, on February 13, 1896 (Letter 41, not included here), where he wrote: 'I am continually occupied with psychology – it is really *meta*psychology'. What is striking about Freud's use of the term in the present letter is his equation of metapsychology with biology. The term first appeared in print in Chapter XII (C) of *The Psychopathology of Everyday Life* (1901*b*), *RSE*, **6**, 222, and then not until the paper on 'The Unconscious' (1915*e*), ibid., **14**, 161, after which it came into frequent use.]

4 [Cf. some earlier remarks on phantasies in Drafts L and M, pp. 275 and 278 above.]

5 [The latter part of this theory was in fact incorporated into *The Interpretation of Dreams* (1900*a*). See, for instance, a well-known passage in Chapter VII (C) (*RSE*, **5**, 501 ff.). It remained an essential element in Freud's theory of the formation of dreams and reappears, for instance, very clearly stated, in 'An Evidential Dream' (1913*a*), ibid., **12**, 271 ff., as well as in Lecture XIV of the *Introductory Lectures* (1916–17*a*), ibid., **15**, 197 ff. – It will be noticed that a little earlier in this letter Freud seems still to be accepting the traumatic aetiology of the neuroses. See footnote 2, p. 287 above.]

LETTER 97[1]

. . . I have started on a new case, so I am approaching it without any foregone conclusions. To begin with, of course, everything is fitting together beautifully. He is a young man of twenty-five, who can scarcely walk owing to stiffness of the legs, spasms, tremors, etc. A safeguard against any wrong diagnosis is provided by the accompanying anxiety, which makes him cling to his mother's apron-strings, like the baby that lies hidden behind. The death of his brother and the death of his father in a psychosis precipitated the onset of his condition, which has been present since he was fourteen. He feels ashamed in front of anyone who sees him walking in this way and he regards that as natural. His model is a tabetic uncle, with whom he already identified himself at the age of thirteen on account of the accepted aetiology (leading a dissolute life). Incidentally, he is a regular bear in physique. [275]

Please observe that the shame is merely appended to the symptoms and must relate to other precipitating factors. He volunteered himself that his uncle was in fact not the least ashamed of his gait. The connection between his shame and his gait was a rational one many years ago, when he had gonorrhoea which was naturally noticeable in his gait, and even some years earlier, too, when constant (aimless) erections interfered with his walking. Besides this, the cause of his shame lay deeper. He told me that last year, when they were living on the [river] Wien (in the country), which[2] suddenly began to rise, he was seized with a terrible fear that the water would come into his bedroom – that is to say, his room would be flooded, and during the night. Please notice the ambiguity of the expression: I knew he had wetted his bed when he was a child. Five minutes later he told me of his own accord that while he was at school he still regularly wetted his bed and that his mother had threatened that she would come and tell the masters and all the other boys about it. He had felt tremendous anxiety. So that is where the shame belongs. The whole story of his youth on the one hand has its climax in the leg symptoms and on the other hand releases the affect belonging to it, and the two are soldered together only for his internal perception. The whole lost story of his childhood has to be inserted in between them.

Now, a child who has regularly wetted his bed till his seventh year (without being epileptic or anything of the kind) must have had sexual experiences in his earlier childhood. Spontaneous or by seduction? That [276]

1 [Dated Vienna, September 27, 1898.]

2 [At this point *Anf.*, 284, inexplicably inserts '*Donau*' ('Danube').]

is the position, and it must also contain the more precise determination – in regard to his legs.

. . . . . .

LETTER 101[1]

. . . In the first place: a small bit of my self-analysis has forced its way through, and confirmed that phantasies are products of later periods and are projected back from the then present on to the earliest childhood, and the manner in which this occurs has also emerged – once more a verbal link.[2]

To the question: 'what happened in earliest childhood?' the answer is 'nothing'. But the germ of a sexual impulse [*Regung*][T] was there. The thing would be easy and nice to tell you; but would take up half a dozen pages if I wrote it out, so I keep it for our meeting at Easter with some other information about my early years.

Besides this I have found another psychical element which I regard as of general significance and as being a preliminary stage of symptoms (even before phantasy).

(January 4.) I got tired yesterday, and today I cannot go on writing along the lines I intended because the thing is growing. There is something in it. It is dawning. In the next few days there will certainly be some addition to it. I will write to you then, when it has become clear. I will only reveal to you that the dream pattern is capable of the most general application, that the key to hysteria as well really lies in dreams. I understand now, too, why, in spite of all my efforts, I have not yet finished the dream book. If I wait a little longer, I shall be able to describe the psychical process in dreams in such a way that it also includes the process in the formation of hysterical symptoms [*Symptombildung*]. So let us wait.[3]

. . . . . .

1 [Dated Vienna, January 3 and 4, 1899.]

2 [This new piece of self-analysis is no doubt the concealed autobiographical episode described in the paper on 'Screen Memories' (1899*a*): cf. *RSE*, **3**, 294.]

3 [Freud had been aware of the close connection between dreams and neuroses for a long time. See the 'Project' of 1895, pp. 361 and 366 below; also Draft N, p. 283 above.]

LETTER 102[1]

. . . Some other things of less importance have turned up – for instance, [277]
that hysterical headaches rest on an analogy in phantasy which equates the top with the bottom end of the body (hair in both places – cheeks [*Backen*] and buttocks [*Hinterbacken* (literally 'hind-cheeks')] – lips [*Lippen*] and labia [*Schamlippen* (literally 'shame-lips')] – mouth = vagina), so that an attack of migraine can be used to represent a forcible defloration, while nevertheless the whole ailment also represents a situation of wish fulfilment.[2] The determining action of sexuality becomes ever clearer. In one woman patient (whom I have set right with the key of phantasy) there were constant states of despair with a melancholic conviction that she was no use, was incapable of anything, etc. I always thought that in her early childhood she had witnessed an analogous state, a genuine melancholia, in her mother. This was in accordance with the earlier theory but two years brought no confirmation of it. And now it has turned out that when she was a girl of fourteen she discovered that she had *atresia hymenalis* [an imperforate hymen] and was in despair that she would be no use as a wife: melancholia – that is, fear of impotence. Other states, in which she cannot make up her mind to choose a hat or a dress, go back to her struggle at the time when she had to choose her husband.

With another woman patient I have convinced myself that there really is such a thing as hysterical melancholia and what its indications are. I have also noted how the same memory appears in the most numerous translations [*Übersetzungen*] and I have gained a first glimpse of melancholia occurring through summation. This patient is, moreover, totally anaesthetic, as she should be according to an idea dating back to the earliest period of my work on the neuroses [p. 228 above].

Of a third woman I have had this most interesting information. An important and wealthy man (a bank director), aged about sixty, came to see me and entertained me with the peculiarities of a girl with whom he has a liaison. I threw out a guess that she was probably quite anaesthetic. On the contrary, she has from four to six orgasms during one coitus. But – at the very first approach she is seized with a tremor and immediately afterwards falls into a pathological sleep; while she is in this she talks as though she was in hypnosis, carries out post-hypnotic suggestions and has complete amnesia for the whole condition. He is [278]

1 [Dated Vienna, January 16, 1899.]

2 [This reappears in Chapter VI (E) of *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 346.]

going to marry her off, and she will certainly be anaesthetic with her husband. The old gentleman, through the possibility of being identified with the immensely powerful father of her childhood, evidently has the effect of being able to set free the libido attached to her phantasies. Instructive![1]

. . . . . .

LETTER 105[2]

. . . My last generalization[3] has held good and seems inclined to grow to an unpredictable extent. It is not only dreams that are wish fulfilments but hysterical attacks as well. This is true of hysterical symptoms but probably of every neurotic event too, for I recognized it long ago of acute delusional insanity.[4] Reality – wish fulfilment. It is from this pair of opposites that our mental life springs. I believe I now know what determines the distinction between dreams and symptoms, which make their way into waking life. It is enough for a dream to be the wish fulfilment of the repressed thought, for dreams are kept apart from reality. But a symptom, set in the midst of life, must be something else besides: it must also be the wish fulfilment of the repressing thought. A symptom arises where the repressed and the repressing thought can come together in the wish fulfilment. A symptom is the wish fulfilment of the repressing thought when, for instance, it is a punishment, a self-punishment, the final replacement of self-gratification, of masturbation.

This key opens many doors. Do you know, for instance, why X.Y. suffers from hysterical vomiting? Because in phantasy she is pregnant, because she is so insatiable that she cannot put up with not having a baby by her last phantasy-lover as well. But she must vomit too, because in that case she will be starved and emaciated, and will lose her beauty and no longer be attractive to anyone. Thus the sense of the symptom is a contradictory pair of wish fulfilments.[5]

[279] Do you know why our friend E.,[6] whom you know, turns red and

1 [These examples show how the traumatic theory was giving way to the importance of phantasies (footnote 2, p. 287 above).]

2 [Dated Vienna, February 19, 1899.]

3 [See Letter 101, p. 302 above.]

4 [In Section III of the first paper on the neuropsychoses of defence (1894*a*), *RSE*, **3**, 54 ff. Freud had also 'long ago' recognized this for hysterical symptoms (see p. 283 and footnote 2 above).]

5 [The last two paragraphs are taken over, only slightly enlarged, into Chapter VII (C) of *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 509.]

6 [See footnote 1, p. 270 above.]

sweats as soon as he sees one of a particular category of acquaintances, especially at the theatre? He is ashamed. No doubt; but of what? Of a phantasy in which he figures as the deflowerer of every person he meets. He sweats as he deflowers, he works very hard at it. An echo of this meaning finds voice in him, like the resentment of someone defeated, every time he feels ashamed in front of someone: 'Now the silly goose thinks I am ashamed in front of her. If I had her in bed, she would see how little embarrassment I feel with her!' And the time at which he directed his wishes on to this phantasy has left its trace on the psychical complex which releases the symptom. It was the Latin class. The auditorium of the theatre reminds him of the classroom; he always tries to get the same regular seat in the front row. The *entr'acte* is the school '*Respirium*'[1] and the 'sweating' meant '*operam dare*' [working] in those days. He had a dispute with the master over that phrase. Moreover, he cannot get over the fact that later, at the university, he failed to pass in botany; he carries on with it now as a 'deflorator'. It is true that he owes his capacity for breaking into a sweat to his childhood – to the time when (at the age of three) his brother poured bathwater and soapsuds over his face when he was in the bath – a trauma, though not a sexual one. And why was it that at Interlaken, when he was fourteen, he masturbated in such a remarkable attitude in the WC? It was only to get a view of the Jungfrau [literally 'maiden']; and since then he has never had a sight of another – at all events *ad genitalia*. He has avoided this intentionally, to be sure, or why else does he have affairs only with actresses?

. . . . . .

LETTER 125[2]

. . . Not long ago I had what may have been a first glimpse of something new. I have before me the problem of 'choice of neurosis'. When does a person become hysterical instead of paranoic? A first crude attempt, made at a time when I was trying to storm the citadel by force, put forward the view that it depended on the age at which the sexual traumas occurred – on the subject's age at the time of the experience. [Cf. p. 256 ff. above.] I gave that up long ago and was left without a clue till a few days ago, when a link with the theory of sexuality dawned on me.

The lowest sexual stratum is auto-erotism, which does without any [280]

1 [Derived from *respirare*: to breathe, therefore by implication: the school 'breather', the school break.]

2 [Dated Vienna, December 9, 1899.]

psychosexual aim and demands only local feelings of satisfaction. It is succeeded by allo-erotism (homo- and hetero-erotism); but it certainly also continues to exist as a separate current. Hysteria (and its variant, obsessional neurosis) is allo-erotic: its main path is identification with the person loved. Paranoia dissolves the identification once more; it re-establishes all the figures loved in childhood which have been abandoned (cf. my discussion of exhibitionist dreams),[1] and it dissolves the ego itself into extraneous figures.[2] Thus I have come to regard paranoia as a forward surge of the auto-erotic current, as a return to the standpoint prevailing then. The perversion corresponding to it would be what is known as 'idiopathic insanity'.[3] The special relations of auto-erotism to the original 'ego' would throw a clear light on the nature of this neurosis. At this point the thread breaks off.[4]

. . . . . .

1 [See *The Interpretation of Dreams* (1900*a*), which had been published a few days before this letter was written, *RSE*, **4**, 215–20.]

2 [Cf. some remarks in the Schreber analysis (1911*c*): 'Paranoia decomposes just as hysteria condenses. Or rather, paranoia resolves once more into their elements the products of the condensations and identifications which are effected in the unconscious.' Ibid., **12**, 43.]

3 ['*Originäre Verrücktheit*.' A concept current in German psychiatry in the latter half of the nineteenth century.]

4 [With this apparent prevision of narcissism, Freud was entering a completely new field of ideas.]

PROJECT FOR A SCIENTIFIC PSYCHOLOGY

(1950 [1895])

EDITORS' INTRODUCTION

[ENTWURF EINER PSYCHOLOGIE]

GERMAN EDITIONS

1950 In *Aus den Anfängen der Psychoanalyse*, edited by Marie Bonaparte, Anna Freud & Ernst Kris, London: Imago Publishing Co., 371–466. [283]
1987 *GW*, **Nachtr.**, 387–477.

ENGLISH TRANSLATIONS

['Project for a Scientific Psychology']
1954 In *The Origins of Psycho-Analysis*, edited as above, London: Imago Publishing Co.; New York: Basic Books, 347–445. (Tr. James Strachey.)
1966 *SE*, **1**, 295–387. (Tr. James Strachey, completely revised.)

The present translation is a thoroughly revised and corrected reprint of the *SE* version, based on the 1987 *GW* revision of the German transcription. The editorial apparatus, too, has been thoroughly revised (see p. xxx above). The German title ('Sketch of a Psychology') was chosen by the editors of the *Anfänge*; the English title was chosen by the translator. The original carries no title. This work, Freud's neuropsychological *magnum opus*, is also included in *NSW*, **4**.

(1) *Historical Summary*

In a letter written to Wilhelm Fliess[1] on April 27, 1895 (Freud, 1950*a*, Letter 23), Freud complained because he was so much involved in his 'Psychology for Neurologists': 'I am positively devoured by it, till I am really overworked and have to break off. I have never experienced such a powerful preoccupation. And will anything come of it? I hope so, but it is a difficult and slow business.' In another letter a month later, May 25, 1895 (Letter 24), this 'Psychology' was further explained: 'It has beckoned to me from afar since time immemorial, but now that I have met with the neuroses it has come that much the nearer. I am vexed by two intentions: to discover what form the theory of psychical functioning will take if a quantitative line of approach, a kind of economics of nervous force, is introduced into it, and, secondly, to extract from psychopathology a yield for normal psychology. It is in fact impossible to form a satisfactory general view of neuropsychotic disorders unless they can be linked to [284]

1 See p. 203 above.

clear hypotheses upon normal psychical processes. I have devoted every free minute of the last few weeks to work like this; I have spent the night hours from eleven till two with imaginings, transpositions and guesses like these; and I have never stopped till I came up against some absurdity or till I had truly and seriously overworked, so that I found I had no interest left for my daily medical activity. You will have to wait a long time yet for any results.' Yet soon he became more optimistic: on June 12 (Letter 25) he could report that the 'psychological construction looks as though it would succeed, which would give me immense pleasure. Of course nothing certain can be said as yet. To make an announcement on this now would be like sending the six-months' foetus of a girl to a ball.' And on August 6 (Letter 26) he announced that 'after long reflection, I believe I have reached an understanding of pathological defence and at the same time of many important psychological processes.' Almost at once, however, there came a further hitch. On August 16 (Letter 27) he wrote: 'I have had a peculiar experience with my $\phi\psi\omega$.[1] No sooner had I made my alarming announcement and called for your congratulations after climbing a secondary peak than I met with fresh difficulties and found I had not enough breath left for the new task. So I quickly made up my mind, threw down the whole alphabet and persuaded myself that I took no interest in it whatever.' And later in the same letter: 'The "Psychology" is really a cross to me. Anyhow, skittles and mushroom-hunting are far healthier. After all, I wanted to do no more than explain defence, but I was led from that into explaining something from the centre of nature. I have had to work through the problem of quality, sleep, memory – in fact, the whole of psychology. Now I want to hear no more about it.'

Soon after this, on September 4, Ernest Jones tells us (1953, 418), Freud visited Fliess in Berlin. Conversations with his friend evidently helped to clear his thoughts, for the composition of the 'Project' followed at once upon this visit. Literally, at once, for 'while I was still in the railway carriage', wrote Freud on September 23 (Letter 28), 'I began a summary account of my $\phi\psi\omega$ for your criticism.' And this in fact constitutes the first few pencilled sheets of the surviving draft of the 'Project' as we possess it today. He went on to describe how he had since been adding to what he had written. 'It makes a portly volume already, no more than a scribble, of course, but, as I hope, a basis for your additions to which I attach great expectation.
[285] My rested brain now makes child's play of the difficulties that were left over.' It was on October 8 that Freud sent Fliess what he had so far completed, in two notebooks (Letter 29). 'They have been scribbled out entirely since my return and will tell you little that is new. I have held back a third notebook which deals with the psychopathology of repression, because it only takes the subject up to a certain point. From there I have had to carry the work on afresh in sketches, and I have been alternately proud and happy about it and ashamed and wretched; until now, after an excess of mental torment, I tell myself apathetically that it does not fit together yet and perhaps never will. What I cannot fit together is not the mechanism of it – I would be patient over that – but the explanation of repression, though clinical knowledge about it has, incidentally, made great advances.' This third notebook has not survived, but Freud continued to struggle with it. A week later, October 15 (Letter 30), the subject is once more thrown aside as unsolved, but on October 20 (Letter 32) there is an outburst of much greater optimism: 'In the course of a busy night . . . the

1 As will be seen later, these and several other alphabetical symbols were employed by Freud in his 'Project'.

barriers were suddenly raised, the veils fell away, and it was possible to see through from the details of the neuroses to the determinants of consciousness. Everything seemed to fit in together, the gears were in mesh, the thing gave one the impression that it was really a machine and would soon run of itself. The three systems of neurons, the free and bound conditions of quantity, the primary and secondary processes, the main trend and the compromise trend of the nervous system, the two biological rules of attention and defence, the indications of quality, reality and thought, the state of the psychosexual groups, the sexual determination of repression, and, finally, the determinants of consciousness as a perceptual function – all this fitted together and still fits together! Of course, I cannot contain myself with delight.'[1] But the cheerful spell lasted only a short time. On November 8 (Letter 35) he reported having thrown the whole of the psychology manuscripts into a drawer 'where they must sleep till 1896'. He had felt overworked, irritated, confused and incapable of mastering the stuff, so he had put it all aside and turned to other matters. And on November 29 (Letter 36) he wrote: 'I can no longer understand the state of mind in which I hatched out the "Psychology"; I cannot make out how I came to inflict it on you.' Nevertheless, only a month later he sent Fliess the long letter of January 1, 1896 (Letter 39), which consists in the main of an elaborate revision of some of the fundamental positions adopted in the 'Project'. This can be found printed below as an Appendix to the 'Project' itself. And with this the 'Project' dis- [286]
appears from view, till its re-emergence some fifty years later with the rest of Freud's forgotten letters to Fliess. Only the ideas contained in it persisted, and eventually blossomed out into the theories of psychoanalysis.

(2) *The Text and its Translation*

As is shown in the bibliography above (p. 309), the first published version of the German text of the work, included in *Aus den Anfängen der Psychoanalyse*, appeared in London in 1950, and an English translation four years later. Some doubt was thrown on the accuracy of that first published German version, and it was clear that, before a revised translation was made, the first thing was to establish a secure German text. This was achieved through the kindness of Mr Ernst Freud, who arranged for the preparation of a photostat of the manuscript, which Strachey could examine at leisure.[2]

Examination of the manuscript quickly confirmed the presence of many divergences from the printed version. The translator was thus faced with a position differing from what he had to meet in the bulk of Freud's writings. Elsewhere, a reader who is doubtful or suspicious about the accuracy of the rendering can almost always consult a reliable German text. Here, unluckily, no such printed text was available. So the translator of the *SE* bore a special responsibility, for the reader was entirely at his mercy, and his treatment of the text had to be adapted to this situation. His judgement was governed by two considerations: he aimed at producing something that would be intelligible and readable, and in a tolerable English style, and he aimed at rendering what he believed to be the author's meaning with as

1 The 'Project' itself will make plain the meaning of these various captions.

2 The manuscript of the 'Project' consists of 100 sheets – 80 small ones, measuring 25 x 20 cm, and 20 large ones, measuring 35 x 25 cm approximately. The large sheets start with the beginning of 'Part III' (p. 384 below). The first four and a half small sheets, containing the first two sections, are evidently those written (in pencil) on the train (p. 310 above).

much exactitude as possible. These two aims may often be in conflict, but in the case of so difficult and so important a work as this, and in the circumstances that have just been mentioned, his translation had to be weighted more than ever on the side of accuracy.

Freud's handwriting is not in the present instance particularly hard to decipher
[287] by anyone familiar with the Gothic script, and there are not in fact many debatable points in the text itself. It was almost literally true of Freud that (as Ben Jonson says of Shakespeare) 'he never blotted a line', and page after page of his writing is completely free from alteration: here, in some forty thousand words of the closest reasoning, there are altogether just over twenty corrections. Thus, it is not in connection with textual matters that problems and questions arise – though it will be seen that there were a number of accidental omissions and misreadings in the printed text – but rather in connection with the interpretation of Freud's expressions and with the best way of presenting them to the reader.

To begin with the simpler points. Freud was not a meticulously careful writer, and a certain number of obvious slips occur. These are silently corrected in our version, except where the mistake is a doubtful one or of special importance. Freud's punctuation is unsystematic (a comma may be omitted or a bracket opened and not closed) and in any case often differs from English usage. This is even more true of his paragraphing, which, moreover, is not always easily assessed. In our version, therefore, we have not thought it necessary to follow the original invariably in either of these points. On the other hand, we have adhered strictly to his very characteristic and very un-English method of underlining: Freud underlines any word or phrase or sentence which strikes him as specially important.[1] Another of his methods of emphasis – by writing a word or phrase in Latin instead of Gothic script – we have thought it unnecessary to note. In most of these respects, incidentally, our treatment agrees with that in the *Anfänge*.

But the main problem raised by Freud's manuscript is his use of abbreviations. These are of various kinds. They reach their maximum in the first four and a half pages – the portion which he wrote in pencil on the train. This is no less clearly written than the rest, perhaps even more clearly. But not only are individual words abbreviated, as often elsewhere, but the sentences themselves are framed in telegraphic style: definite and indefinite articles omitted, sentences without any principal verb. Here, for instance, is a literal translation of the first sentence of the work: 'Intention to furnish natural-scientific psych., i.e. to represent psych. processes as quantit. determinate states of specifiable material particles, thus to make perspicuous and free from contradiction.' Where the sense is not in doubt, the sensible plan is obviously to fill in the gaps, indicating with square brackets only the less certain completions of
[288] the meaning. After these first four and a half pages there is a complete change: the abbreviations thereafter are almost entirely restricted to individual words.

Here again, however, there are distinctions to be made. (*a*) First, there are, of course, abbreviations universally used: for instance, '*usw*' for '*und so weiter*' ('etc.') and '*u*' for '*und*' ('and'). (*b*) Then there are others, regularly used by Freud in his writing, such as shortening the terminations in '*ung*' and '*ungen*' to '*g*' and '*gen*': '*Besetzg*' for '*Besetzung*' ('cathexis'). (*c*) Next come abbreviations of particular terms

1 In a very few places, always notified in a footnote, we have added italics of our own for the sake of clarity.

used very frequently in the work or in certain passages of it. Typical of these is '*Cschr*', which stands for '*Contactschranke*' ('contact barrier'). This word is written out in full on its first appearance, but abbreviated ever afterwards. Similarly, with such frequent terms as '*Qualz*', which stands for '*Qualitätszeichen*' ('indication of quality'). In all these kinds of abbreviation there is evidently no point in annoying the reader by imitating them in the translation: there is never any doubt as to what Freud meant by them. (*d*) We now reach what are beginning to approach symbols rather than abbreviations, the alphabetical signs of which Freud was always fond: for instance, '*N*' for '*Neuron*' ('neuron'), '*W*' for '*Wahrnehmung*' ('perception'), '*V*' for '*Vorstellung*' ('idea'). Along with these may be classed '*Er*', his very common abbreviation for '*Erinnerung*' ('memory'). All of these are used by Freud with great frequency, though from time to time (and inconsistently) he will write the words out in full. Since here again there is no doubt about the meaning, we uniformly adopt the unabbreviated form.[1] (*e*) But there remains a fifth class to which this does not apply. The Greek letters ϕ, ψ and ω (*phi*, *psi* and *omega*) are used by Freud in this work as shorthand signs for quite complex notions duly explained when they are introduced; and these are accordingly left unchanged in our translation.

Here is a plausible theory about ω and its relation to *W*. Freud had started with two 'systems' of neurons, which, for fairly obvious reasons, he named ϕ and ψ. He then found that he required a symbol for a third system of neurons, concerned with [289]
conscious perceptions. Now, on the one hand, another Greek letter would be appropriate – like the other two, perhaps, from the end of the Greek alphabet. On the other hand, some allusion to its function was desirable. As we have seen, an upper-case '*W*' stands for 'perception' ('*Wahrnehmung*') and the Greek *omega* (ω) looks very much like a lower-case '*w*'. Freud considered consciousness to be a perceptual function. So this might be why he chose 'ω' for the conscious system. The joke, or at all events half of it, disappears in English; but nevertheless it seemed essential to keep here to the 'ω'. The distinction between '*W*' and 'ω' is quite unmistakable in Freud's manuscript; but it is perhaps the most serious defect in the *Anfänge* that it very often fails to observe it, sometimes with unfortunate results to the meaning. A general perceptual function is assigned by Freud to the ϕ system of neurons, with the ω system being assigned the special perceptual function of *consciousness* (or 'sensation' [*Empfindung*] as Freud sometimes calls it here; pp. 333 and 413 below).[2]

1 A qualification is called for here in the case of '*W*' and '*Er*'. It will be found that these sometimes stand respectively for '*Wahrnehmungsbild*' ('perceptual image') and '*Erinnerungsbild*' ('mnemic image') instead of for '*Wahrnehmung*' and '*Erinnerung*'. The only way of deciding for certain on the correct expanded version depends on the fact that the longer terms are of neuter gender whereas the shorter ones are feminine. There is usually an article or an adjective to make the decision possible; but this is one of those cases in which the reader must depend on the Editors' judgement, and it is also one in which differences sometimes arise between the present version and the *Anfänge*.

2 The relation between perception (*Pcpt.*) and consciousness (*Cs.*) continued to trouble Freud throughout his theoretical writings. This was already apparent when he first introduced the ω (*Cs.*) neurons, almost as an afterthought, on p. 333 below. He decided to move these neurons to a position between ϕ and ψ in his January 1, 1896 revision of the 'Project' (Appendix B, p. 413 below). Then in *The Interpretation of Dreams* (1900*a*) he moved the system *Cs.* back to its previous position (or at least to a position beyond the unconscious memory systems, immediately preceding or coinciding with motor discharge). Subsequently, he combined the systems *Pcpt.* and *Cs.*, in his later topographic models from 1917 onwards (Freud, 1916–17*f* [1915]). But this presented fresh problems which he deferred to the (missing) metapsychological paper on consciousness. The problems seem

The heir to the ω system in Freud's later metapsychological writings is not the *Pcpt*. system, but rather the *Cs*. system. The *Pcpt*. system on the other hand is clearly equivalent to the ϕ system.

Last of all among these alphabetic signs come Q and its mysterious companion $Q\eta$. Both of them undoubtedly stand for 'quantity'. But why this difference between them? And, above all, why the Greek *eta* with the smooth breathing? There is no question that the difference is a real one, though Freud nowhere explicitly announces it or explains it. There is a place (on p. 345 below) where he began by writing '$Q\eta$' and then scratched out the 'η', and there is another passage (p. 387) where he speaks of a 'quantity composed of Q and $Q\eta$'. But in fact, only a page before these words (p. 386), he does seem to explain the difference himself. Q, so he seems to say, is 'external quantity' and $Q\eta$ 'psychical quantity' – though the wording is not totally unambiguous. Perhaps what Freud had in mind was a distinction between endogenous $Q\eta$ and exogenous Q, which does not actually enter the organism but does influence the passage of $Q\eta$ within it. (In either event, this is the solution he adopted in his January 1, 1896 revision; see Appendix B below.) It must be added that Freud himself sometimes seems inconsistent in his use of the signs, and very often indeed he uses the word '*Quantität*' written out in full or slightly abbreviated. Evidently the reader must be left to find his own solution for this enigma, and we therefore scrupulously follow the manuscript in printing 'Q' or '$Q\eta$' or 'quantity'.

In general, indeed, as we have said, we keep as close as possible to the original: wherever we diverge in important respects, and whenever we are in serious doubts, we register the fact either by square brackets or by a footnote. It is here that we differ fundamentally from the editors of the *Anfänge*, who make all their changes without any indication whatever. In view of this fact, we have thought it necessary, where our version diverges substantially from that in the *Anfänge*, to adduce the German original in a footnote. Minor inaccuracies, such as the frequent mistakes over Q and $Q\eta$, have been passed over in silence; but, even so, the necessity for correcting the numerous errors in the earlier printed German version has involved
[290] us in a plethora of footnotes. Many readers will no doubt be irritated by this; but it will enable those who possess the *Anfänge* and *Origins* edition to bring them more closely into line with Freud's original manuscript. The new German (*GW Nachtragsband*) edition is, however, entirely consistent with the present translation, as revised.

(3) *The Significance of the Work*

Has it been worthwhile to take such elaborate measures over the text of the 'Project'? Freud himself would very probably have said 'no'. He dashed it off in two or three weeks, left it unfinished, and criticized it severely at the time of writing it. Later in life he seems to have forgotten it or at least never to have referred to it. And when

only to have become soluble when Freud suggested that the id 'has a world of perception of its own' arising from sensory terminal organs in the interior of the body (1940*a* [1938]; *RSE*, **23**, 179). This remark appeared to recognize that feelings of pleasure and unpleasure are registered in a *Cs*. system located between the id and the ego (see Solms, 1997*a*, Solms & Nersessian, 1999), independently of the *Pcpt*. system, which faces the outside world, but Freud denied that implication (Freud, 1940*a* [1938]; *RSE*, **23**, 146). – The notion that affective consciousness is endogenous is, incidentally, current in modern neuroscience, which also recognizes its primacy over exteroceptive consciousness (Panksepp, 1998, Damasio, 1999). The ramifications are discussed fully in Solms, 2013*a*.

in his old age he was presented with it afresh, he did his best to destroy it.[1] Can it, then, be of any value?

There are grounds for thinking that its author took a jaundiced view of it, but its value can be defended along two very different lines.

Anyone who examines the indexes to the later volumes of the *RSE* will be surprised to find in every single one of them references, and often very many references, back to the Fliess letters and to the 'Project'. And, as a corollary, he will find in the footnotes to the pages that follow very many references forward to the later volumes of the *RSE*. This circumstance is an expression of the remarkable truth that the 'Project', in spite of being ostensibly a neurological document, contains within itself the nucleus of a great part of Freud's later psychological theories. In this respect, its discovery was not only of historical interest; it actually threw light for the first time on some of the more obscure of Freud's fundamental hypotheses. The help given by the 'Project' towards an understanding of the theoretical seventh chapter of *The Interpretation of Dreams* (1900*a*) is discussed in some detail in the Editors' Introduction to that work (*RSE*, **4**, xviii ff.). But in fact the 'Project', or rather its invisible ghost, haunts the whole series of Freud's theoretical writings to the very end.[2]

The fact that there are many evident lines of connection between the 'Project' and [291]
Freud's later views must not, however, lead us to overlook the basic differences between them.

In the first place, it will be immediately obvious that there is very little indeed in these pages to anticipate the technical procedures of psychoanalysis. Free association, the interpretation of unconscious material, the transference – these are barely hinted at. Only in the passages on dreams is there any anticipation of later clinical developments. Clinical material is indeed largely restricted to Part II, which deals with psychopathology. Parts I and III are in the main built up on theoretical and *a priori* foundations. In this connection a further contrast is apparent. Whereas in the largely disconnected clinical portion (Part II) sexuality figures very prominently, in the theoretical portions (Parts I and III) it plays only a small part. Actually, at the very time at which Freud was composing the 'Project', his clinical researches into the neuroses were chiefly focused on sexuality. It may be recalled that on the very same day (January 1, 1896) on which he sent Fliess his long letter revising some of the theoretical foundations of the 'Project' (p. 413 below), he also sent him the 'Christmas Fairy Tale' (p. 248 above), which was a preliminary study for his second paper on the neuropsychoses of defence (1896*b*) and centred on the effects of sexual experiences. This uncomfortable divorce between the clinical and theoretical significance of sexuality was only to be resolved a year or two later by Freud's self-analysis, which led to his recognition of infantile sexuality and to the basic importance of unconscious drive impulses.

This brings us to another major difference between Freud's theories in the 'Project' and his later ones. Most of the emphasis in the picture here is upon the environment's impact upon the organism and the organism's reaction to it. It is true

1 For an account of this, see Chapter XIII of the first volume of Jones's biography (1953, 316–18).

2 The curious student may follow this lengthy trail more particularly through the letters to Fliess of January 1 and December 6, 1896 (pp. 413 below and 260 above), Chapter VII of *The Interpretation of Dreams* (1900*a*), 'The Two Principles of Mental Functioning' (1911*b*), the metapsychological papers of 1915, *Beyond the Pleasure Principle* (1920*g*), *The Ego and the Id* (1923*b*), the 'Mystic Writing-Pad' (1925*a*) and, finally, the *Outline of Psychoanalysis* (1940*a* [1938]).

that, in addition to external stimuli, there are endogenous excitations; but their deeper nature is hardly considered. The future 'drives' are only shadowy entities, with scarcely even a name. The interest in these endogenous excitations is restricted in the main to secondary, 'defensive' operations and their mechanisms. It is a curious fact that what was later to be the almost omnipotent 'pleasure principle' is here regarded almost solely as an inhibiting mechanism. Indeed, even in *The Interpretation of Dreams* (1900*a*), published four years later, it is still always called the 'unpleasure
[292] principle'. Internal forces are scarcely considered except in terms of their reactions to external ones. The id, in short, is still to be discovered.[1] On the other hand, we should be careful not to overstate this emphasis on environmental factors; Freud does after all declare here that the whole organ of the mind is nothing but a 'sympathetic ganglion' (p. 327 below) and that unmediated exposure of the ψ system to endogenous $Q\eta$ provides 'the *mainspring* of the psychical mechanism' (p. 340).

Bearing this in mind, we can perhaps arrive at a more general view of the development of Freud's theories. What we have in the 'Project' is a pre-id – a 'defensive' – description of the mind, notwithstanding its acknowledged embodiment. With the recognition of infantile sexuality and the psychological analysis of the sexual drives, Freud's interests were diverted from defence and for some twenty years he devoted himself largely to the study of the id itself. It was only when that study seemed more or less exhausted that he returned, in the last period of his work, to a consideration of defence. It has often been pointed out that it is in the 'Project' that we can find a foretaste of the structural ego which emerges in *The Ego and the Id* (1923*b*), *RSE*, **19**. But this is quite naturally so. There were bound to be similarities between a pre-id and a post-id picture of ego processes.

Reflection upon these aspects of the 'Project' is likely to suggest another possible source of interest in the work – one which is remote from psychoanalysis and which cannot be dealt with adequately here. Freud's attempted approach more than a hundred years ago to a description of mental phenomena in physiological terms might well seem to bear a resemblance to certain modern approaches to the same problem.[2] It has been suggested latterly that the human nervous system may be regarded in its workings as similar or even identical to a computer – both of them machines for the reception, storage, processing and output of information. It has been plausibly pointed out that in the complexities of the 'neuronal' events described here by Freud, and the principles governing them, we may see more than a hint or two at the hypotheses of information theory and cybernetics in their application to the nervous system. To take a few instances of this similarity of approach, we may note first Freud's insistence on the prime necessity for providing the machine with a 'memory'; again, there is his system of 'contact barriers', which enables the machine to make a suitable 'choice', based on the memory of previous events, between alternative lines of response to an external stimulus; and, once more, there is, in Freud's account of the mechanism of perception, the introduction of the fundamental notion of feedback as
[293] a means of correcting errors in the machine's own dealings with the environment.

1 The general account of the workings of the mind in Chapter VII (B) of *The Interpretation of Dreams* (1900*a*) still shows much resemblance to the 'Project', especially in its stress on the mind as a *receiving* apparatus: 'all our psychical activity starts from stimuli (whether internal or external) and ends in innervations' (*RSE*, **5**, 480).

2 Cf., in particular, the very elaborate and detailed examination, along such lines, of the earlier edition of the 'Project' by Pribram (1962, 1965) and the important study by Pribram & Gill (1976).

Such resemblances, and others, to the extent they are valid, would no doubt be fresh evidence of the originality and fertility of Freud's ideas, and it may be an alluring possibility to see him as a precursor to latter-day cognitive science. At the same time there is a risk that enthusiasm may lead to a distortion of Freud's use of terms and may read into his sometimes obscure remarks modern interpretations that they will not bear. For this revised edition, the Editor has accordingly drawn attention to such resemblances only insofar as they place the 'Project' in historical context, and thereby enable modern readers to better understand Freud's obscure neuroscientific terminology and concepts.[1]

We must remember that Freud himself ultimately threw over the whole neurological framework. Nor is it hard to guess why. For he found that his neuronal machinery had no means of accounting for what, in *The Ego and the Id* (1923*b*), *RSE*, **19**, 15, he described as being 'in the last resort our one beacon-light in the darkness of depth psychology' – namely, 'the property of being conscious or not'.[2] In his last work, the posthumous *Outline of Psychoanalysis* (1940*a* [1938]), ibid., **23**, 142, he declared that the starting point of his investigation into the structure of the psychical apparatus 'is provided by a fact without parallel, which defies all explanation or description – the fact of consciousness', and he adds this footnote: 'One extreme line of thought, exemplified in the American doctrine of behaviourism, thinks it possible to construct a psychology which disregards this fundamental fact!' It would be perverse indeed to seek to impute a similar disregard to Freud himself.

The opening sentence of the 'Project' states a philosophical assumption that Freud soon abandoned, namely that psychology can only be a natural science if it represents psychical processes as physical ones. With the introduction of the notion that psychical processes are 'in themselves unconscious' (Freud, 1900*a*; ibid., **5**, 482) this assumption fell away, and psychoanalysis took 'its place as a natural science like any other', at least as far as Freud was concerned (1940*a* [1938]; ibid., **23**, 143). This coincided with his final acceptance that psychical locality can only be adequately dissected in a *functional* manner (Freud, 1900*a*; ibid., **5**, 479) – as Freud seems to have progressively realized during the present work. (See also Letter 52, p. 260 f. above.) Ironically, given the almost total lack of scientific methods for determining the physical correlates of the mental processes that he was discovering throughout the 1890s by purely clinical methods, by remaining on psychological ground Freud was able to base his psychology on a sounder empirical footing than the 'Project' provided (cf. Solms, 1998, 2000*a*, Solms & Saling, 1986). For all the appearance of exact science, it is easy to forget, as Freud himself admitted to Fliess, that the only methods available in 1895 to base his psychology on a physiological footing were 'imaginings, transpositions and guesses' (Letter 24, p. 310 above). It is small wonder that he abandoned this approach, and reverted to a purely clinical method. The 'Project' must remain a torso, disavowed by its creator.

The Editor of the *SE* had the advantage of discussing some parts of the translation with Professor Merton M. Gill, of the State University of New York, and of adopting a number of his valuable suggestions.

1 The footnotes in question are derived mainly from Pribram & Gill (1976) and Solms (1996).

2 See p. 335 below: 'no attempt, of course, can be made to explain *how it is* that excitatory processes in the ω neurons bring consciousness along with them' (emphasis added).

KEY TO ABBREVIATIONS IN THE 'PROJECT'

[294]

Q	Quantity (in general, or of the order of magnitude in the external world) – See p. 386 below
$Q\eta$	Quantity (endogenous, or of the intercellular order of magnitude) – See p. 330 below
ϕ	system of permeable neurons
ψ	system of impermeable neurons
ω	system of qualitative neurons
W	perception (*Wahrnehmung*)
V	idea (*Vorstellung*)
M	motor image

PROJECT FOR A SCIENTIFIC PSYCHOLOGY

[PART I] GENERAL SCHEME

Introduction

The intention is to furnish a psychology that shall be a natural science: [295]
that is, to represent psychical processes as quantitatively determinate states of specifiable material particles, thus making those processes perspicuous and free from contradiction. Two principal ideas are involved: [1] What distinguishes activity from rest is to be regarded as Q,[1] subject to the general laws of motion. (2) The neurons[2] are to be taken as the material particles.

N[3] and $Q\eta$ – Similar experiments are now frequent.[4]

[1] (*a*) *First Principal Theorem*

The Quantitative Conception

This is derived directly from pathological clinical observation especially where excessively intense ideas were concerned – in hysteria and obsessions, in which, as we shall see, the quantitative characteristic emerges

1 [In a footnote to his contribution to *Studies on Hysteria* (1895*d*), *RSE*, **2**, 174 *n*., Breuer remarks that 'the conception of the energy of the central nervous system as being a quantity distributed over the brain in a changing and fluctuating manner is an old one'. He goes on to quote from the early-nineteenth-century French physician Georges Cabanis (1824, **3**, 153). A discussion of Q can be found in Appendix C, p. 417 below.]

2 [The term 'neuron', as a description of the basic unit of the nervous system, had just recently been introduced by Waldeyer in 1891. Freud's own histological researches had led him towards the same finding. See especially Freud (1884*f*), *NSW*, **1**, and see also a note on this in *RSE*, **3**, 233 *n*. 2. For a discussion of Freud's role in the establishment of the neuron doctrine, see Shepherd (1991).]

3 [We owe to the editors of the *GW*, **Nachtr**. the realization that (with very few exceptions) Freud used the Latin letter *N* to abbreviate 'neuron' and the Gothic equivalent to abbreviate 'nerve'. These abbreviations are hereafter silently spelt out.]

4 [Cf., for instance, Exner (1894), with a similar title and a similar programme, very differently carried out.]

more plainly than in the normal.[I] Processes such as stimulus, substitution, conversion and discharge [*Abfuhr*][T], which had to be described there [in connection with those disorders], directly suggested the conception of neuronal excitation [*Nervenerregung*][T] as quantity in a state of flow.[t] It seemed legitimate to attempt to generalize what was recognized there. Starting from this consideration, it was possible to lay down a basic principle of neural activity in relation to *Q*, which promised to be highly enlightening, since it appeared to comprise the entire function. This is the principle of neuronal inertia: that neurons tend to divest themselves of *Q*. On this basis the structure and development as well as the functions [of neurons] are to be understood.[2]

abführen

[296]

Erregung

In the first place, the principle of *inertia* explains the structural dichotomy [of nervous tissue] into motor and sensory as a contrivance for neutralizing the reception of $Q\eta$ by giving it off. Reflex movement is now intelligible as an established form of this giving off: the principle provides the motive [*Motiv*][T] for reflex movement. If we go further back from here, we can in the first instance link the nervous system,[3] as inheritor of the general irritability of protoplasm, with the irritable external surface [of an organism], which is interrupted by considerable stretches of non-irritable surface. A primary nervous system makes use of this $Q\eta$ which it has thus acquired, by giving it off through a connecting path to the muscular mechanisms, and in that way keeps itself free from stimulus. This discharge represents the primary function of the nervous system. Here is room for the development of a secondary function. For among the paths of discharge those are preferred and retained which involve a cessation of the stimulus: *flight from the stimulus*. Here in general there is a proportion between the *Q* of excitation and the effort necessary for the flight from the stimulus, so that the principle of *inertia* is not upset by this.

The principle of inertia is, however, breached from the first owing to another circumstance. With an [increasing] complexity of the interior

[297]

1 ['Excessively intense ideas' are discussed in Section 1 of Part II, p. 372 below. This 'economics of nervous force' is the origin of the economic point of view in Freud's later metapsychology.]

2 [In the extended form described below (p. 321), this is what was later known as the 'principle of constancy' and attributed by Freud to Fechner. This is by no means Freud's first mention of it. A discussion of its significance and of its many occurrences throughout Freud's writings can be found in an Editors' Appendix to the first paper on the neuropsychoses of defence (1894*a*), *RSE*, **3**, 59. It has been suggested – questionably – that the concept may be equated with that of homoeostasis (see Cannon, 1932).]

3 [Here and elsewhere this stands for '*Nsy*' (with a Latin *N*) in the MS. It seems probable that Freud was using this as an abbreviation for the ordinary '*Nervensystem*' and not for '*Neuronensystem*' (as expanded in *Anf.*, *passim*). The former is in fact written out in full in the MS. on pp. 338 and 349 below.]

[of the organism], the nervous system receives stimuli from the somatic element itself – endogenous stimuli – which have equally to be discharged. These have their origin in the cells of the body and give rise to the major needs: hunger, respiration, sexuality.[1] From these the organism cannot withdraw as it does from external stimuli; it cannot employ their Q for flight from the stimulus. They only cease subject to particular conditions, which must be realized in the external world. (Cf., for instance, the need for nourishment.) In order to accomplish such an action (which deserves to be named 'specific'[2]), an effort is required which is independent of endogenous $Q\eta$ and in general greater, since the individual is being subjected to conditions which may be described as *the exigencies of life*.[3] In consequence, the nervous system is obliged to abandon its original trend to inertia (that is, to bringing the level [of $Q\eta$] to zero). It must put up with [maintaining] a store of $Q\eta$ sufficient to meet the demand for a specific action. Nevertheless, the manner in which it does this shows that the same trend persists, modified into an endeavour at least to keep the $Q\eta$ as low as possible and to guard against any increase of it – that is, to keep it constant. All the functions of the nervous system can be comprised either under the aspect of the primary function or of the secondary one imposed by the exigencies of life.[4]

[2] (*b*) *Second Principal Theorem*

The Neuron Theory

The idea of combining with this $Q\eta$ theory the knowledge of the neurons arrived at by recent histology is the second pillar of this thesis. The main substance of these new discoveries is that the nervous system consists of [298]
distinct and similarly constructed neurons, which have contact with one another through the medium of a foreign substance, which terminate

1 [These 'endogenous stimuli' are the precursors to the 'drives'. Cf. the Editors' Note to 'Drives and their Vicissitudes', *RSE*, **14**, 101 f. See also p. 420 below.]

2 [The 'specific' action reappears, under other names, in (for instance) 'Repression' (1915*d*), *RSE*, **14**, 130, and in *Civilization and its Discontents* (1930*a*), ibid., **21**, 62. But it had been mentioned earlier than this in Part III of the first paper on anxiety neurosis (1895*b*), ibid., **3**, 97 (where it was termed the 'specific or adequate action'), and earlier still in Draft E, p. 220 above ('the specific reaction').]

3 [This phrase, too, occurs regularly in other works, e.g. in *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 505, though Freud later preferred the Greek word '*Ananke*'. Cf. *Civilization and its Discontents* (1930*a*), ibid., **21**, 126.]

4 [See footnote 2, p. 320 above. – These two functions are of course precursors to the metapsychological primary and secondary processes and to the link between the latter and the reality principle.]

upon one another as they do upon portions of foreign tissue, [and] in which certain lines of conduction are laid down insofar as they [the neurons] receive [excitations] through cell processes [dendrites] and [give them off][1] through an axis cylinder [axon]. They have in addition numerous ramifications of varying calibre.

Besetzung

If we combine this account of the neurons with the conception of the $Q\eta$ theory, we arrive at the idea of a *cathected* [*besetzten*][T] neuron filled with a certain $Q\eta$ while at other times it may be empty.[2] The principle of inertia [p. 320 above] finds its expression in the hypothesis of a *current* passing from the cell's paths of conduction or processes [dendrites] to the axis cylinder. A single neuron is thus a model of the whole nervous system with its dichotomy of structure, the axis cylinder being the organ of discharge. The secondary function [of the nervous system], however, which calls for the accumulation of $Q\eta$ [p. 321], is made possible by the assumption of resistances which oppose discharge; and the structure of neurons makes it probable that the resistances are all to be located in the *contacts* [between one neuron and another], which in this way assume the value of *barriers*. The hypothesis of *contact barriers* is fruitful in many directions.[3]

[3] *The Contact Barriers*

The first justification for this hypothesis arises from the consideration that there the path of conduction passes through undifferentiated protoplasm instead of (as it otherwise does, within the neuron) through differentiated protoplasm, which is probably better adapted for conduction. This gives us a hint that conductive capacity is to be linked with

1 [The MS. has '*abnehmen* (take off)', probably a slip of the pen and emended in *Anf.*, 382, to '*abgeben* (give off)'.]

2 [The notion of 'cathexis' ('*Besetzung*') had been used by Freud already, but not much earlier, in *Studies on Hysteria* (1895*d*), *RSE*, **2**, 79. A full discussion of its use is given in the Editors' Appendix referred to in footnote 2, p. 320 above, *RSE*, **3**, 59. In modern neurophysiological terms, the 'cathexis' of a neuron in the sense used here is described as its 'potential'. When the potential of a neuron reaches a certain magnitude, discharge, an action current (the nerve impulse) occurs, and then the potential is gradually reconstituted. (See Appendix C below.)]

3 [In modern neuroscience, the contact barriers are called 'synapses'. The term was introduced by Foster & Sherrington in 1897, two years after Freud wrote this. Sherrington (1906) elaborated further on the *functions* of the synapse some ten years later when increasing evidence had accumulated to the effect that these involved a delay in speed of transmission, i.e. some form of resistance requiring a summation of impulses (see Shepherd, 1991, 227–8). Almost a century later, Eric Kandel won the Nobel Prize for elucidating the molecular synaptic mechanisms of memory. Freud's contribution to the development of this concept is acknowledged by Brazier (1959) and Triarhou & del Cerro (1985) among others. – After this point the MS. ceases to be written in pencil, and the abbreviations become less drastic (see p. 312 above).]

differentiation, so that we may expect to find that the process of conduction itself will create a differentiation in the protoplasm and consequently an improved conductive capacity for subsequent conduction. [299]

Furthermore, the theory of contact barriers can be turned to advantage as follows. A main characteristic of nervous tissue is memory: that is, quite generally, a capacity for being permanently altered by single occurrences – which offers such a striking contrast to the behaviour of a material that permits the passage of a wave movement and thereafter returns to its former condition. A psychological theory deserving any consideration must furnish an explanation of 'memory'. Now any such explanation comes up against the difficulty that it must assume on the one hand that neurons are permanently different after an excitation from what they were before, while nevertheless it cannot be disputed that, in general, fresh excitations meet with the same conditions of reception as did the earlier ones. It would seem, therefore, that neurons must be both influenced and also unaltered, unprejudiced. We cannot offhand imagine an apparatus capable of such complicated functioning; the situation is accordingly saved by attributing the characteristic of being permanently influenced by excitation to one class of neurons, and, on the other hand, the unalterability – the characteristic of being fresh for new excitations – to another class.[1] Thus has arisen the current distinction between 'perceptual cells' and 'mnemic cells' – a distinction, however, which fits into no other context and cannot itself appeal to anything in its support.

The theory of contact barriers, if it adopts this solution, can express it in the following terms. There are two classes of neurons: [1] those which allow $Q\eta$ to pass through as though they had no contact barriers and which, accordingly, after each passage of excitation are in the same state as before, and (2) those whose contact barriers make themselves felt, so that they only allow $Q\eta$ to pass through with difficulty or partially. The latter class may, after each excitation, be in a different state from before and they thus afford a *possibility of representing memory*.

Thus there are *permeable* neurons (offering no resistance and retaining nothing), which serve for perception, and *impermeable* ones (loaded [300]

1 [The incompatibility between the functions of perception and memory had been remarked on by Breuer in a footnote to his theoretical contribution to *Studies on Hysteria* (1895*d*), *RSE*, **2**, 168 *n*. Freud returned to the subject in his letter to Fliess of December 6, 1896 (p. 261 above). He dealt with it often in his published writings: in Chapter VII (B) of *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 480 ff., and again, much later, in Chapter IV of *Beyond the Pleasure Principle* (1920*g*), ibid., **18**, 24 f., and in his paper on the 'Mystic Writing-Pad' (1925*a*), ibid., **19**, 228.]

with resistance, and holding back $Q\eta$), which are the vehicles of memory and so probably of psychical processes in general. Henceforward I shall call the former system of neurons[1] ϕ and the latter ψ.

It will be well now to clear our mind as to what assumptions about the ψ neurons are necessary in order to cover the most general characteristics of memory. This is the argument. They are permanently altered by the passage of an excitation. If we introduce the theory of contact barriers: their contact barriers are brought into a permanently altered state. And since psych[ological] knowledge shows that there is such a thing as overlearning[2] on the basis of memory, this alteration must consist in the contact barriers becoming more capable of conduction,[3] less impermeable, and so more like those of the ϕ system. We shall describe this state of the contact barriers as their degree of *facilitation* [*Bahnung*].[4] We can then say: *Memory is represented by the facilitations existing between the ψ neurons.*

If we were to suppose that all the ψ contact barriers were equally well facilitated, or (what is the same thing) offered equal resistance, then the characteristics of memory would evidently not emerge. For, in relation to the passage of an excitation, memory is evidently one of the powers which determine and direct its pathway, and, if facilitation were everywhere equal, it would not be possible to see why one pathway should be preferred. We can therefore say still more correctly that *memory is represented by the differences in the facilitations between the ψ neurons*.[5]

What, then, does the *facilitation* in the ψ neurons depend on? According to psych[ological] knowledge, the memory of an experience (that is, its continuing operative power) depends on a factor which is called the magnitude of the impression and on the frequency with which the same impression is repeated. Translated into theory: Facilitation depends on the

1 ['*System von Neuronen*' in the MS., not '*Nsy*'. Cf. p. 320 *n*. 3 above.]

2 ['*Ein Über-Erlernen*.' The term was translated 'a re-learning' in the *SE*. Cf. pp. 360 and 402 f. below.][t]

3 ['*Leitungsfähiger*' in the MS. *Anf*., 384, prints this as '*leistungsfähiger*' ('more efficient'). In modern neuroscience, the concept of 'synaptic plasticity' still rests (as Freud describes here) on activity-dependent properties of the neuron. However, these properties include synaptogenesis, i.e. growth of new synaptic connections. Similarly, Freud's distinction between the permeable and impermeable systems of neurons would today be linked with the low *number* of synaptic relays in the fast circuits leading from the sensory periphery (ϕ) in comparison with those in the central organ (ψ).]

4 [The word 'facilitation' as an equivalent of the German '*Bahnung*' seems to have been introduced by Sherrington a few years after the 'Project' was written. The German word, however, introduced by Exner (1894), was already in use (cf. p. 384 *n*. 6 below).][t]

5 [The word 'differences' is doubly underlined in the MS.]

$Q\eta$ which passes through the neuron in the excitatory process and on the number of repetitions of the process. From this we see, then, that $Q\eta$ is the operative factor and that *quantity* plus *facilitation* resulting from $Q\eta$ [301] are at the same time something that can replace $Q\eta$.[1]

Here we are almost involuntarily reminded of the endeavour of the nervous system, maintained through every modification, to avoid being burdened by $Q\eta$ or to keep the burden as small as possible. Under the compulsion of the exigencies of life, the nervous system was obliged to lay up a store of $Q\eta$ [p. 321 above]. This necessitated an increase in the number of its neurons and these had to be impermeable. It now avoids, partly at least, being *filled* with $Q\eta$ (cathexis), by setting up *facilitations*. It will be seen, then, that *facilitations serve the primary function* [of the nervous system].

The necessity for finding a place for memory calls for something further from the theory of contact barriers. Every ψ neuron must in general be presumed to have several paths of connection with other neurons – that is, several contact barriers. On this, indeed, depends the possibility of the *choice* that is determined by facilitation [p. 324 above]. It now becomes quite clear that the state of facilitation of one contact barrier must be independent of that of all the other contact barriers of the same ψ neuron, otherwise there would once again be no preference and thus no motive [*Motiv*][T]. From this we can draw a negative conclusion about the nature of the '*facilitated*' state. If we think of a neuron filled with $Q\eta$ – that is, cathected – we can only assume that this Q [*sic*] is uniform over all the regions of the neuron, and therefore over all its contact barriers as well. On the other hand, there is no difficulty in imagining that, in the case of $Q\eta$ in a state of flow, only one particular path through the neuron is taken; so that only one contact barrier is subject to the action of the $Q\eta$ in flow and has facilitation left over from it afterwards. Therefore facilitation cannot have its basis in a cathexis that is held back, for that would not produce the differences in the facilitations of the contact barriers of the same neuron.[2]

It remains to be seen in what else facilitation consists. A first idea might be: in the absorption of $Q\eta$ by the contact barriers. Perhaps light will be

1 [This point is developed further below on p. 344. What is implicitly formulated here is an Ohm's law of neuronal function, in terms of which the magnitude of the current ($Q\eta$ in a state of flow) is determined by the potential (cathexis) of the neurons involved in relation to the degree of synaptic resistance (facilitation) between them. It is important to note that the strength of a current is not determined solely by the amperage of each action potential, but also – as Freud points out – by the frequency with which the neuron fires (number of action potentials per second). See Pribram & Gill (1976, 34, 66).]

2 [Since, see above, the quantity is uniform over the whole presynaptic neuron.]

thrown on this later. [Cf. p. 341 f. below.] The $Q\eta$ which has left the facilitation behind is no doubt discharged – precisely as a result of the facilitation, which, indeed, increases permeability.[1] Moreover, it is not necessarily the case that the facilitation which remains after a passage of $Q\eta$ is as great as it had to be during the passage. [See p. 341 below.] Pos-
[302] sibly only a quotient of it is left as a *permanent facilitation*. Similarly, it is also impossible to tell yet whether the passage of $Q{:}3\eta$ once is equivalent to the passage of one $Q\eta$ 3 times.[2] All this remains to be considered in the light of later applications of the theory to the psychical facts.

[4] *The Biological Standpoint*

The hypothesis of there being two systems of neurons, ϕ and ψ, of which ϕ consists of permeable elements and ψ of impermeable, seems to provide an explanation of this one of the peculiarities of the nervous system[3] – that of retaining and yet of remaining capable of receiving [p. 323 above]. All psychical acquisition would in that case consist in the organization of the ψ system through partial and locally determined lifting of the resistance in the contact barriers which distinguishes ϕ and ψ. With the advance of this organization the nervous system's capacity for fresh reception would literally have reached a barrier.

Anyone, however, who is engaged scientifically in the construction of hypotheses will only begin to take his theories seriously if they can be fitted into our knowledge from more than one direction and if the arbitrariness of a *constructio ad hoc*[4] can be mitigated in relation to them. It will be objected against our hypothesis of contact barriers that it assumes two classes of neurons with a fundamental difference in their conditions of functioning, though there is at the moment no other basis for the differentiation. At all events, morphologically (that is, histologically), nothing is known in support of the distinction.

Where else are we to look for this division into classes? If possible in the biological development of the nervous system, which, in the eyes of natural scientists, is, like everything else, something that has come about gradually. We should like to know whether the two classes of neurons can have had a different significance biologically, and, if so, by what mechanism they may have developed characteristics so different as

1 [Cf. the first paragraph of this section.]

2 [This last question is answered on p. 346 below.]

3 [The MS. reads '*des Nsy*' (singular) not '*der*' (plural), as implied by *Anf.*, 387.]

4 [Translator's italics.]

permeability and impermeability. What would be most satisfactory, of course, would be if the mechanism we are in search of should itself arise out of the primitive biological part played [by the two classes]; if so, we should have a single answer to both questions.

Let us recall, then, that from the first the nervous system had two functions: the reception of stimuli *from outside* and the discharge of excitations of *endogenous* origin [p. 321 above]. It was from this latter obligation, indeed, that, owing to the exigencies of life, a compulsion [*Zwang*][T] came about towards further biological development [p. 325]. We might then conjecture that it might actually be our systems ϕ and ψ each of which had assumed one of these primary obligations. The system ϕ would be the group of neurons which the external stimuli reach, the system ψ would contain the neurons which receive the endogenous excitations. In that case we should not have *invented* the two [classes], ϕ and ψ, we should have *found* them already in existence.[1] It still remains to identify them with something known to us. In fact, we know from anatomy a system of neurons (the grey matter of the spinal cord) which is alone in contact with the external world, and a superimposed system (the grey matter of the brain) which has no direct[2] peripheral connections but to which the development of the nervous system and the psychical functions are attached. The primary brain[3] fits pretty well with our characterization of the system ψ, if we may assume that paths lead directly, and independently of ϕ, from the brain to the interior of the body.[4] Now, the derivation and original biological significance of the primary brain are not known to anatomists; according to our theory, it would, to put it plainly, be a *sympathetic ganglion*. Here is a first possibility of testing our theory upon factual material.[5] [303]

1 ['*Erfunden*' and '*vorgefunden*'.]

2 [This word was omitted in the *SE*. The peripheral connections in question concern only the external periphery, not the interior of the body (see below).]

3 ['*Das primäre Gehirn*.' This is presumably the prosencephalon (forebrain) which is derived embryologically from the primary cerebral vesicle. The secondary and tertiary vesicles become the mesencephalon and rhombencephalon (brainstem).]

4 [Forebrain communication with the interior of the body is mediated primarily by the hypothalamus – Sherrington's 'head ganglion' of the autonomic nervous system – independently of the paths for external conduction (ϕ). The autonomic functions of the hypothalamus were not well understood until the work of Cannon in the 1920s (see p. 320 *n*. 2 above). The hypothalamic sympathetic pathway was discovered in 1930. The more recently understood 'need detector' mechanisms of the hypothalamus are directly equivalent to the ψ function that Freud describes here. Other, non-forebrain structures serve related functions, particularly the deep nuclei of the brainstem (see footnote 3 above) but they in turn interact with the hypothalamus. Freud might have had in mind the 'great limbic lobe' of Broca, the core of the future limbic system or 'visceral brain', the primitive affective functions of which had already been intuited by Broca (1878).]

5 [A second such possibility is mentioned below, p. 329. The 'sympathetic' nervous system had been described by Galen in classical Roman times already, but Freud's suggestion that the forebrain (ψ) serves a sympathetic function in relation to the major needs of the body (p. 321

We will provisionally regard the ψ system as identified with the grey matter of the brain. It will now easily be understood from our introductory biological remarks [p. 325 above] that it is precisely ψ that is subjected to further development through an increase in the number of neurons and an accumulation of Q. And it will now be realized how expedient it is that ψ should consist of impermeable neurons, since otherwise it would be unable to meet the requirements of the specific action [p. 321]. But how did ψ arrive at the characteristic of impermeability? After all, ϕ too has contact barriers; if *they* play no part whatever, why should ψ's contact barriers? To assume that there is an ultimate difference between the valence of the contact barriers of ϕ and of ψ has once more an unfortunate tinge of arbitrariness [cf. p. 326], though it would be possible to follow a Darwinian line of thought and to appeal to the fact of impermeable neurons being indispensable and to their surviving in consequence.

[304] Another way out seems more fruitful and more modest. Let us recall that the contact barriers of the ψ neurons too are in the end subjected to facilitation and that it is $Q\eta$ that facilitates them [p. 324]. The greater the $Q\eta$ in the passage of excitations the greater the facilitation: that means, however, the closer the approach to the characteristics of ϕ neurons [p. 324]. Let us therefore attribute the differences not to the neurons but to the quantities with which they have to deal. It must then be supposed that quantities pass on to the ϕ neurons against which the resistance of the contact barriers does not come into account, but that only such quantities reach the ψ neurons as are of the same order of magnitude as that resistance.[1] In that case a ϕ neuron would become impermeable and a ψ neuron would become permeable – if we could exchange their locality and connections; they retain their characteristics, however, because the ϕ neuron is linked only with the periphery and the ψ neuron only with the interior of the body. A difference in their essence is replaced by a difference in the environment to which they are destined.

Now, however, we must examine our assumption – whether we may say that the quantities of stimulus reaching the neurons from the external periphery are of a higher order than those from the internal periphery of the body. There is, in fact, much that speaks in favour of this.

In the first place there is no question but that the external world is the

above) was a radical proposal. The implication that all learning is 'sympathetic' cannot be said to have been demonstrated 'upon factual material' before the second half of the twentieth century, when the central role of the limbic system in memory processes was demonstrated (see footnote 4, p. 327 above).]

1 [I.e. as the resistance of the contact barriers. Cf. p. 330 below.]

origin of all major quantities of energy, since, according to the discoveries of physics, it consists of powerful masses which are in violent motion and which transmit their motion. The system ϕ, which is turned towards this external world, will have the task of discharging as rapidly as possible the $Q\eta$s penetrating to the neurons, but it will in any case be exposed to the effect of major Qs.

To the best of our knowledge, the system ψ is out of contact with the external world; it only receives Q on the one hand from the ϕ neurons themselves, and on the other from the cellular elements in the interior of the body, and it is a question now of making it probable that these quantities of stimulus are of a comparatively low order of magnitude. We may be disturbed at first by the fact of having to attribute to the ψ neurons two such different sources of stimulus as ϕ and the cells of the interior of the body; but it is precisely here that we receive conclusive assistance from the recent histology of the nervous system. This shows that the *termination* of a neuron and the *connection* between neurons are con- [305]
structed on the same type, and that neurons terminate on one another as they do on somatic elements [cf. p. 321 f. above]; probably, too, the functional side of the two processes is of the same kind. It is likely that similar quantities are dealt with at the nerve-endings and in the case of intercellular conduction. We may also expect that *endogenous* stimuli are of this same *intercellular* order of magnitude.[1] Incidentally, we have here a second opportunity for testing the theory [pp. 327–8].[2]

[5] *The Problem of Quantity*

I know nothing about the absolute magnitude of intercellular stimuli; but I will venture on the assumption that they are of a comparatively small order of magnitude and of the same order as the resistances of the contact barriers. This, if it is so, is easily understandable. With this assumption, the essential sameness of the ϕ and ψ neurons is saved, and

1 [This was restated by Freud in *Beyond the Pleasure Principle* (1920*g*), *RSE*, **18**, 29. The whole of Chapter IV of that work seems to look back to this section of the 'Project'.]

2 [The whole question of the special characteristics of that portion of the mental apparatus which is in contact with the external world continued to interest Freud throughout his life. But the most elaborate of his later discussions of the question is once more in *Beyond the Pleasure Principle* (1920*g*), ibid., **18**, 25 f., where the treatment verges on the physiological and is distinctly reminiscent of the present passage apart from the fact that it incorporates his 1896 revision of the 'Project' (Appendix B below) and equates the systems *Pcpt.* and *Cs.* in accordance with his 1916–17*f* [1915] revision. See Editors' Introduction above, p. 313 *n.* 2. The topic is, of course, closely related to that of reality-testing, which is reached in Section 15, p. 349 below.]

their difference in respect of permeability is explained biologically and mechanically.[1]

Here there is a lack of evidence; all the more interesting are certain perspectives and conceptions which arise from this assumption. In the first place, if we have formed a correct impression of the magnitude of the Qs in the external world, we shall ask ourselves whether, after all, the original trend of the nervous system to keep $Q\eta$ at [the level of] zero
[306] [pp. 320 and 321 above] is satisfied with rapid discharge – whether it is not already at work during the reception of stimuli. We discover, in fact, that the ϕ neurons do not terminate at the periphery freely [i.e. without coverings] but in cellular structures which receive the exogenous stimulus in their stead. These 'nerve-ending apparatuses', [using the term] in the most general sense, might well have it as their purpose not to allow exogenous Qs to make an undiminished effect upon ϕ but to damp them down.[2] They would then have the significance of Q screens, through which only *quotients* of exogenous Qs will pass.

This accordingly tallies with the fact that the other kind of nerve-endings, the *free* ones, without [sensory] end-organs, is by far the more common in the internal periphery of the body. No Q screens seem to be needed there, probably because the $Q\eta$s which have to be received there do not require to be reduced first to the intercellular level, but are at that level from the start.

Since the Qs which are absorbed[3] by the endings of the ϕ neurons can be calculated, this perhaps gives us a means of forming some idea of the magnitudes that pass between ψ neurons, these being, as we know, of the same kind as the resistances of the contact barriers [p. 328 f. above].

Here, furthermore, we have a glimpse of a trend which may perhaps govern the construction of the nervous system out of several systems: an ever-increasing keeping off of $Q\eta$ from the neurons. [See p. 339 below.] Thus the structure of the nervous system would serve the purpose of

1 ['*Und mechanisch*' in the MS. These last two words are omitted in *Anf.*, 390. – It is worth noting that all through the present work Freud groups the explanations of the phenomena he is studying under two headings: 'mechanical' and 'biological'. The distinction has already appeared above on p. 326. It is discussed on p. 347 below, and is exemplified later, for instance, on pp. 384–6. By 'mechanical' (for which he sometimes uses 'automatic' as a synonym) he means that the phenomenon in question is determined directly by contemporary physical events; by 'biological' he means that it is determined genetically – by its survival value for the species.]

2 [This precise point is once more made in *Beyond the Pleasure Principle* (1920g), *RSE*, **18**, 27 f. Further elaboration of the point on p. 333 f. below makes clear that the Q is not merely damped but actually transduced by the Q screens (i.e. sensory receptors).]

3 ['*aufgenommen*.' Translated 'received' in the *SE*. The sense seems to imply 'transmitted' as the quantities in question could only be comparable after the exogenous Q had been transduced by the endings of the ϕ neurons.]

keeping off Qη from the neurons and its function would serve the purpose of *discharging* it [*der Abfuhr*]^{T}. *abführen*

[6] *Pain*[1]

All contrivances of a biological nature have limits to their efficiency, beyond which they fail. This failure is manifested in phenomena which border on the pathological – which might be described as normal prototypes of the pathological. We have found that the nervous system is contrived in such a way that the major external *Q*s are kept off from ϕ and still more from ψ: [by][2] the nerve-ending screens, [and by] the merely indirect connection between ψ and the external world. Is there a phenomenon which can be brought to coincide with the failure of these contrivances? Such, I think, is *pain*. [307]

Everything that we know of pain fits in with this. The nervous system has the most decided inclination to a *flight from pain*. We see in this a manifestation of the primary trend against a raising of *Qη* tension, and we infer that pain consists in *the irruption of large Qs into ψ*.[3] The two trends are in that case a single one. Pain sets the ϕ as well as the ψ system in motion, there is no obstacle to its conduction, it is the most imperative of all processes. Thus the ψ neurons seem permeable to it; it therefore consists in the action of *Q*s of a comparatively high order.

The precipitating causes of pain are on the one hand increase of quantity: every sensory excitation, even of the highest sense organs, tends towards pain with an increase of the stimulus. This is to be understood unhesitatingly as a failure [of the contrivance]. On the other hand, there is pain where the external quantity is small, and in such cases this is regularly linked with a breach in continuity:[4] that is, an external *Q* which acts directly on the ends of the ϕ neurons and not through the nerve-ending apparatuses produces pain. *Pain* is thus characterized as an irruption of

1 ['*Schmerz*.' Not long before, perhaps early in January, 1895, Freud had given another, and somewhat cryptic, explanation of pain. See Draft G (p. 232 f. above).]

2 [This clause, which is much abbreviated in the MS., is filled in in *Anf*., 391, by the words '*dienen diesem Zweck*' ('serve this purpose'). Not so in the *GW* version.]

3 [This theory of pain was introduced again by Freud in *Beyond the Pleasure Principle* (1920*g*), *RSE*, **18**, 29–30, and in *Inhibitions, Symptoms and Anxiety* (1926*d*), ibid., **20**, 150–2. There, however, the quantitative factor of unpleasure is incorporated and more weight is therefore given to the endogenous reaction to the external painful stimulus (see Section 7 and p. 345 f. below). In modern neurophysiology, too, pain is conceptualized in both sensory and affective terms. See Craig (2003).]

4 ['*Continuitätstrennung*' in the original. The meaning is not entirely clear but presumably implies a breach in the continuity of the stimulus barrier provided by the *Q* screens.]

excessively large Qs into ϕ and ψ: that is, of Qs which are of a still higher order than the ϕ stimuli.

The fact that pain passes along all pathways of discharge is easily understandable. On our theory that Q produces facilitation [p. 324 above], pain no doubt leaves permanent facilitations behind in ψ – as though there had been a stroke of lightning – facilitations which possibly do away with the resistance of the contact barrier entirely and establish a pathway of conduction there such as there are in ϕ.[1]

[7] *The Problem of Quality*

Hitherto, nothing whatever has been said of the fact that every psychological theory, apart from what it achieves from the point of view of natural science, must fulfil yet another major requirement. It should explain to us what we are aware of, in the most puzzling fashion, through
[308] our 'consciousness'; and, since this consciousness knows nothing of what we have so far been assuming – quantities and neurons – it should explain this lack of knowledge to us as well.

We at once become clear about a postulate which has been guiding us up to now. We have been treating psychical processes as something that could dispense with this awareness through consciousness, as something that exists independently of such awareness. We are prepared to find that some of our assumptions are not confirmed through consciousness. If we do not let ourselves be confused on that account, it follows, from the postulate of consciousness providing neither complete nor trustworthy knowledge of the neural processes, that these are in the first instance to be regarded to their whole extent as unconscious[2] and are to be inferred like other natural things.[3]

In that case, however, a place has to be found for the content of consciousness in our quantitative ψ processes. Consciousness gives us what are called *qualities* – sensations [*Empfindungen*] which are *different* in a great multiplicity of ways and whose *difference* is distinguished according to its relations with the external world. Within this difference there are series, similarities and so on, but there are in fact no quantities in it.

1 [The topic is taken up again below, in Section 12 (p. 345).]

2 [This is a good instance of the fact that in German the word '*unbewusst*', which we translate as 'unconscious', is a *passive* verbal form and might be rendered 'unconscioused'.]

3 [It may be observed that this is a statement made about *physiological* entities – 'neuronal processes'. Some time was still to elapse before Freud could make exactly the same statement about *psychical* events. See Editors' Introduction, p. 317 above, and *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 547 f.]

It may be asked how qualities originate and *where* qualities originate. These are questions which call for the most careful examination and which can only be treated roughly here.

Where do qualities originate? Not in the external world. For, out there, according to the view of our natural science, to which psychology too must be subjected here, there are only masses in motion and nothing else. In the ϕ system perhaps? That tallies with the fact that the qualities are linked with perception, but it is contradicted by everything that rightly argues in favour of the seat of consciousness being in the *upper* storeys of the nervous system.[1] In the ψ system then. Against this, however, there is a weighty objection. During perception the ϕ and the ψ systems are in operation together; but there is one psychical process which is no doubt performed exclusively in ψ – reproducing [of past perceptions] or remembering – and this, speaking generally, is *without quality*. Remembering brings about *de norma*[2] [normally] nothing that [309]
has the peculiar character of perceptual quality. Thus we summon up courage to assume that there is a third system of neurons – ω perhaps [we might call it] – which is excited along with perception, but not along with reproduction, and whose states of excitation give rise to the various qualities – are, that is to say, *conscious sensations*.[3]

If we keep firmly to the fact that our consciousness furnishes only *qualities*, whereas science recognizes only[4] *quantities*, a characterization of the ω neurons emerges, as though by rule of three[t]. For whereas science has set about the task of tracing all the *qualities* of our sensations back to *external quantities*, it is to be expected from the structure of the nervous system that it consists of contrivances for transforming external *quantity* into quality; and here the original trend to keep off *quantity* seems to triumph once more [p. 330 f. above]. The nerve-ending apparatuses were a screen that would only allow quotients of external quantity to act upon ϕ, while ϕ at the same time dealt with the rough discharge of quantity. The system ψ was already protected against higher orders of quantity and had to do only with intercellular magnitudes. As a further step, it is to be suspected that the system ω is moved by still smaller quantities. It would seem as though the characteristic of quality (that is, conscious sensation) comes about only where quantities are so far as

1 [But see Editors' Introduction, p. 313 *n.* 2 above.]

2 [Translator's italics.]

3 [Freud's choice of the Greek *omega* to indicate the conscious system of perceptual neurons is discussed in the Editors' Introduction above, p. 313.]

4 ['*nur*' in the MS. Omitted in *Anf.*, 394.]

possible excluded. It cannot be got rid of entirely, since we must think of the[1] ω neurons too as cathected with $Q\dot{n}$ and striving towards discharge.[2]

At this point, however, we are met by what seems to be an immense difficulty. We have seen [p. 324 f. above] that permeability depends on the effect of $Q\dot{n}$, and the ψ neurons are already impermeable. With still smaller $Q\dot{n}$, the ω neurons would have to be still more impermeable. But that is a characteristic that we cannot grant to the vehicles of consciousness. The mutability of their content, the transitoriness of consciousness, the easy linking of qualities simultaneously perceived – all of this tallies only with complete permeability of the ω neurons, together with total *restitutio in integrum*[3] [restoration of their former state]. The ω neurons behave like organs of perception, and in them we could find no place for a memory [p. 323 above]. Permeability, then,
[310] complete facilitation, which does not arise from quantity. From where else [can it arise]?[4]

I can see only one way out of the difficulty: a revision of our fundamental hypothesis about the passage of $Q\dot{n}$. So far I have regarded it only as the transference of $Q\dot{n}$ from one neuron to another. But it must have still another characteristic, of a temporal nature; for the mechanics of the physicists have allowed this temporal characteristic to the other motions of masses in the external world as well. I speak of this as *period* for short.[5] Thus I shall assume that all the resistance of the contact barriers applies only to the transference of Q, but that the *period* of the neuronal motion is transmitted without inhibition in all directions, as though it were a process of induction.[6]

1 [‘*die*’ in the MS.; ‘*diese*’ (‘these’) in *Anf.*, 394.]

2 [But cf. a correction on this point in the revision of the whole theory in the letter of January 1, 1896, pp. 413 ff. below.]

3 [Translator’s italics.]

4 [A further difficulty is the problem of the anatomical location of the ω neurons. If the ψ neurons constitute the forebrain and the ϕ neurons are the perceptual pathways that terminate in the forebrain, where do the ω neurons belong? – These problems disappear with the 1896 revision (Appendix B below). Cf. *Beyond the Pleasure Principle* (1920*g*), *RSE*, **18**, 25 ff.]

5 [Later comments in *Beyond the Pleasure Principle* (ibid., **18**, 8, 29, 31, 59 f.) suggest that Freud had something like amplitude in mind here. Elsewhere he speaks of ‘the rhythm, the temporal sequence of changes, rises and falls in the quantity of stimulus’ (1924*c*), ibid., **19**, 152; see also 1940*a* [1938]; ibid., **23**, 133. – The ‘mechanics of the physicists’ possibly refers to the second law of thermodynamics which deals with change in the organization of energy systems over time (entropy). The first law deals with the conservation of energy (inertia).]

6 [Pribram & Gill (1976, 25) make the important point that if what is registered in ω is something temporal (like amplitude or wave-length or pulse-code) then it is in the nature of *information*, not *energy*. Information is a measure of energy organization, or pattern, not energy amount.]

Here very much remains to be done in the way of physical clarification, for here too the general laws of motion must apply without contradiction. The hypothesis goes further, however, [and assumes] that the ω neurons are incapable of receiving $Q\eta$, but that instead they appropriate the *period* of the excitation and that this state of theirs of being affected by period while they are filled with the minimum of $Q\eta$ is the fundamental basis of consciousness. The ω neurons too have their period, of course; but it is without quality or, more correctly, *monotonous*. Deviations from this psychical period that is specific for them come to consciousness as qualities.

Where do these differences of *period* spring from? Everything points to the sense organs, whose qualities seem to be represented precisely[1] by different periods of neuronal motion. The sense organs act not only as Q screens, like all nerve-ending apparatuses, but also as *sieves*; for they allow the stimulus through from only certain processes with a particular period. They then probably transfer this difference to ϕ, by communicating to the neuronal motion periods which differ in some analogous way (specific energy); and it is these modifications which proceed[2] through ϕ via ψ to ω, and there, where they are almost devoid of quantity, generate conscious sensations of qualities. This transmission of quality is not durable; it leaves no traces behind and cannot be reproduced.[3]

[8] *Consciousness*

It is only by means of such complicated and far from perspicuous hypotheses that I have hitherto succeeded in introducing the phenomena of consciousness into the structure of quantitative psychology. No attempt, of course, can be made to explain how it is that excitatory processes in the ω neurons bring consciousness along with them. It is only a question of establishing a coincidence between the characteristics of consciousness that are known to us and processes in the ω neurons which vary in parallel with them. And this is quite possible in some detail. [311]

A word on the relation of this theory of consciousness to others. According to an advanced mechanistic theory, consciousness is a mere

1 ['*Eben*' in the MS. Omitted in *Anf*., 395.]

2 ['*Die sich . . . fortsetzen*' in the MS. *Anf*., 395, prints '*die sie . . . fortsetzen*' ('which continue them'? the periods). This seems to make less satisfactory sense.]

3 [The doctrine of 'specific energy' of sensory nerves was established by Müller in 1835, before Helmholtz formulated the first law of thermodynamics (in 1860) which gave energy concepts narrowly quantitative connotations. For a discussion of the importance of this concept for Freud's metapsychology, see Solms & Saling (1990, 103–10).]

appendage to physiologico-psychical processes and its omission would make no alteration in the psychical passage [of events]. According to another theory, consciousness is the subjective side of all psychical events and is thus inseparable from the physiological mental process
Seele [*Seelenvorgang*][T]. The theory developed here lies between these two. Here consciousness is the subjective side of one part of the physical processes in the nervous system, namely of the ω processes; and the omission of consciousness does not leave psychical events unaltered but involves the omission of the contribution from ω.[1]

If we represent consciousness by ω neurons, several consequences follow. These neurons must have a discharge, however small, and there must be a way of filling the ω neurons with $Q\eta$ in the small quota required. The discharge will, like all others, go in the direction of motility; and here it is to be noticed that with the transformation into motion everything in the nature of quality, every peculiarity of period, is lost.[2] The filling of ω neurons with $Q\eta$ can no doubt only proceed from ψ, since we do not wish to admit any direct link between this third system and ϕ [p. 334 *n.* 4 above]. It is not possible to suggest what the original biological value of the ω neurons was.[3]

[312] So far, however, we have given an incomplete account of the content of consciousness. Besides the series of sensory qualities, it exhibits another series very different from that – the series of sensations of *pleasure* [*Lust*][T] and *unpleasure* [*Unlust*], which now calls for interpretation [*Deutung*][T]. Since we have certain knowledge of a trend in psychical life towards *avoiding unpleasure*, we are tempted to identify that trend with the primary trend towards inertia. In that case *unpleasure* would have to be regarded as coinciding with a raising of the level of $Q\eta$ or an increasing quantitative pressure: it would be the ω sensation when there is an increase of $Q\eta$ in ψ. Pleasure would be the sensation of discharge.

1 [A few years earlier than this, in his monograph on aphasia (1891*b*), *NSW*, **4**, Chapter V, Freud had discussed this problem and, under the influence of Hughlings Jackson, had adopted a position much closer to the 'appendage' theory of consciousness described above. This passage is quoted in full as Appendix B to Freud's metapsychological paper on 'The Unconscious' (1915*e*), *RSE*, **14**, 183 ff. The lack of clarity in the present discussion is no doubt an indication that Freud was, in fact, already moving towards his later view that mental events can be both conscious and unconscious. The transition in Freud's views in this respect is summarized in Solms (1998).]

2 [Cf., however, pp. 350 *n.* 4, 359 *n.* 2, 388 *n.* 7 and 411 *n.* 1 below.]

3 [In the case of ϕ and ψ this had been suggested on p. 327 above. In his later writings, Freud suggested that the biological value of consciousness was to perceive 'oscillations in the tension of its drive needs' (1940*a* [1938]), *RSE*, **23**, 179. This view was based on the assumption, articulated in Freud (1911*b*), ibid., **12**, 217, if not before, that consciousness of external qualities was, in fact, an elaboration of its primary interoceptive function described in the next paragraph. (See Editors' Introduction, p. 313 *n.* 2 above.)]

Since ω is assumed [above] to be filled from ψ, the hypothesis would follow that when the level in ψ rises the cathexis in ω increases, and when, on the other hand, that level falls the cathexis diminishes. Pleasure and unpleasure would be the sensations in ω of its own cathexis, of its own level; and here ω and ψ would, as it were, represent intercommunicating vessels.[1] In this manner the quantitative processes in ψ too would reach consciousness, once more as qualities.

The aptitude for perceiving sensory qualities which lie, so to say, in the zone of indifference between pleasure and unpleasure disappears with the [presence of the] feeling of pleasure and unpleasure. This might be translated: the ω neurons show an optimum for receiving the *period* of neuronal motion at a particular [strength of] cathexis; when the cathexis is stronger they produce unpleasure, when it is weaker, pleasure – till, with a lack of cathexis, their capacity for reception vanishes.[2] The corresponding form of motion would have to be constructed on the basis of such data as these.

[9] *The Functioning of the Apparatus*[3]

It is now possible to form the following picture of the functioning of the apparatus constituted by $\phi\psi\omega$.

The amounts of excitation penetrate from outside to the endings of [313]
the ϕ system. They first come up against the nerve-ending apparatuses and are broken up by them into quotients, which are probably of a higher order than intercellular stimuli (perhaps, after all, of the same order?). Here there is a first threshold: below a certain quantity no effective quotient at all comes into being, so that the effective capacity of the *stimuli* is to some extent restricted to *medium* quantities. Besides this, the nature of the nerve-ending coverings[4] acts as a sieve, so that not

1 [See Editors' footnote 1, p. 388 below.]

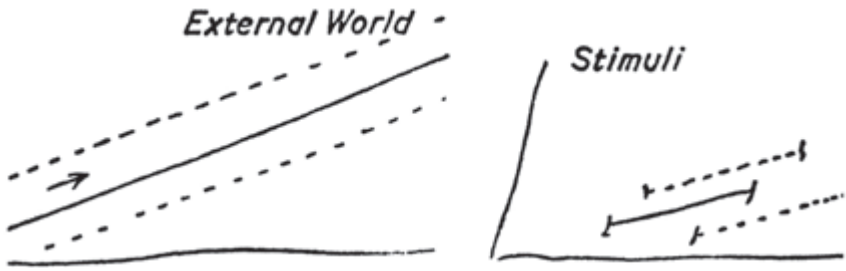
2 [This argument reappears in *Beyond the Pleasure Principle* (1920*g*), *RSE*, **18**, 8–9, where it is attributed to Fechner. – In this section Freud identifies what he was later to call the 'pleasure principle' with the 'principle of constancy'. Very much later on, he distinguished between the two. A full account of his changing views on the subject is given in an Editors' footnote to 'Drives and their Vicissitudes' (1915*c*), ibid., **14**, 106 f. *n*.]

3 [This section of the MS. was, in fact, headed by Freud 'Second Part', which is omitted in *Anf*., 397. The reason for the omission is that Freud started his major division on 'Psychopathology' (p. 372 below) with the same heading – 'Second Part'. The wisest plan is no doubt to follow the *Anfänge* and to disregard the present 'Second Part'. It is a curious fact that these two headings of 'Second Part' are the only numbered divisions made by Freud himself. 'Part I' and 'Part III' were introduced by the editors of the *Anfänge*, and the Arabic sectional numberings were inserted in the *Origins* by the translator.]

4 [*Anf*., 398, has '*Nervendecken*', which would mean 'nerve coverings'. The MS. reads '*Nervenddecken*' which is presumably an abbreviation for '*Nervenenddecken*'.]

every kind of stimulus can operate on the various terminal points [p. 335 above]. The stimuli which actually reach the ϕ neurons have a quantity and a qualitative characteristic;[1] in the external world they form a series of the same quality and of quantity ranging upwards from the threshold to the pain limit.

Whereas in the external world the *processes* exhibit a continuum in two directions, according to quantity and period (quality), the *stimuli* corresponding to them [to the processes] are, as regards quantity, firstly *reduced* and secondly *limited* owing to excision, and, as regards quality, are discontinuous, so that certain periods do not operate as stimuli at all [Fig. 12].



[Fig. 12]

[314] The qualitative characteristic of the stimuli now proceeds unhindered through ϕ by way of ψ to ω, where it generates sensation; it is represented by a particular period of neuronal motion, which is certainly not the same as that of the stimulus, but has a certain relation to it in accordance with a reduction formula which is unknown to us. This period does not persist for long and disappears towards the motor side; nor, since it is allowed to pass through, does it leave any memory behind it.

The quantity of the ϕ stimulus excites the nervous system's[2] trend to discharge, by transforming itself into a proportionate motor excitation. The apparatus of motility is attached directly to ϕ. The quantities which are translated in this way produce an effect far superior quantitatively to themselves, by entering the muscles, glands,[3] etc. – acting there, that is,

1 [For the sake of clarity, it may be pointed out that strictly speaking (in spite of an apparent contradiction in the later part of the present sentence) neither the 'processes' in the external world nor the 'stimuli' that pass through the 'nerve-ending apparatuses' into ϕ, nor the cathexes in ϕ or ψ possess 'quality', but only a qualitative *characteristic* – 'period' – which, when it reaches ω, is *perceived* as quality.]

2 [Here '*Nervensystem*' is written out in full in the MS. Cf. p. 320 above.]

3 [The inclusion of glands here presages the introduction of 'key neurons' on p. 345 below.]

by a *release* [of quantity], whereas between neurons only a *transference* [*Übertragung*]^{T} takes place.[1]

In the ϕ neurons, furthermore, the ψ neurons terminate.[2] To the latter a part of the $Q\eta$ is transferred, but only a part – a quotient, perhaps, corresponding to the magnitude of an intercellular stimulus. At this point the question arises whether the $Q\eta$ transferred to ψ may not increase in proportion to the Q flowing in ϕ, so that a greater stimulus produces a stronger psychical effect. Here a special contrivance seems to be present, which once again keeps off Q from ψ. For the sensory path of conduction in ϕ is constructed in a peculiar fashion. It ramifies continually and exhibits thicker and thinner paths, which end in numerous terminal points – probably with the following significance: a stronger[3] stimulus follows different pathways from a weaker one. [Cf. Fig. 13.][4] For instance, [1]$Q\eta$ will pass only along pathway I and will

[Fig. 13]

transfer a quotient to ψ at terminal α. 2($Q\eta$)[5] will not transfer a double [315]
quotient at α, but will be able to pass also along pathway II, which is narrower, and to open up another terminal point to ψ [at β]. 3($Q\eta$) will open up the narrowest path [III] and will transfer through γ as well. This is how the single ϕ path is relieved of its burden; the larger quantity in ϕ will be expressed by the fact that it cathects several neurons in ψ instead of a single one. The different cathexes of the ψ neurons may in this case be approximately equal. If [1]$Q\eta$ in ϕ gives rise to a cathexis in ψ, then 3($Q\eta$) is expressed by a cathexis in $\psi_1 + \psi_2 + \psi_3$. Thus *quantity* in ϕ is

1 [Cf. transduction at the perceptual end of the apparatus, p. 330 *n*. 2 above.]

2 [The sense implies the opposite: the ϕ neurons terminate on the ψ neurons.]

3 ['*Stärkerer*' in the MS. *Anf*., 399, has '*starker*' ('strong').]

4 [Since ϕ is identified with the spinal sensory nuclei (p. 327 above) and their cranial-nerve equivalents (Freud, 1886*c*; *NSW*, **1**), this figure must depict the ramifications of sensory paths between these nuclei and their forebrain targets. The vertical line in Fig. 13 therefore distinguishes the spinal/cranial-nerve nuclei (ϕ) from the forebrain (ψ).]

5 [So in the MS. *Anf*., 399, alters this and 3($Q\eta$) below to ($Q\eta$)2 and ($Q\eta$)3 respectively.]

expressed by *complication* in ψ. By this means the Q is held back from ψ, within certain limits at least. This is very reminiscent of the conditions of Fechner's law, which might in this way be localized.[1]

In this manner ψ is cathected from ϕ in Qs which are normally small. The quantity of the ϕ excitation is expressed in ψ by complication, its quality is expressed *topographically*, since, according to their anatomical relations, the different sense organs are in communication through ϕ only with particular ψ neurons. But ψ receives cathexis as well from the interior of the body; and it is probable that the ψ neurons should be divided into two groups: the neurons of the *pallium*[2] which are cathected from ϕ and the *nuclear* neurons[3] which are cathected from the endogenous paths of conduction.[4]

[10] *The* ψ *Paths of Conduction*

The nucleus of ψ is connected with the paths by which endogenous quantities of excitation ascend. Without excluding the possibility of these paths being connected with ϕ, we must nevertheless hold to our original assumption that a direct pathway leads from the interior of the body to ψ neurons [p. 327 above]. If this is so, however, ψ is exposed to
[316] Qs on this side without protection and in this fact lies the *mainspring* [*Triebfeder*] of the psychical mechanism.[5]

What we know of the *endogenous* stimuli may be expressed in the assumption that they are of an intercellular nature, that they arise continuously and only periodically become psychical stimuli.[6] We cannot

1 [Fechner's law formulates the relation between changes in the intensity of a stimulus and changes in the resultant sensation. In mathematical terms, it states that sensation varies with the logarithm of the strength of the stimulus. Freud appears to be suggesting that the law comes into operation at this particular junction in the nervous system.]

2 ['*Mantelneurone*.']

3 ['*Kernneurone*.']

4 [Anatomically the 'pallium' of the prosencephalon is the telencephalon, which includes the cerebral cortex and basal ganglia (or 'subpallium'). The 'nucleus' of the prosencephalon is the diencephalon, which includes the hypothalamus (see p. 327 *n.* 4 above) and thalamus (= 'inner chamber'). However, it is important to note that not all telencephalic neurons are activated from the sensory periphery and not all diencephalic ones from the autonomic core. Indeed, some neurons of the diencephalon (the modality-specific relay nuclei) are activated from the sensory periphery, and these provide the principal inputs to the pallium neurons referred to in the text. The division Freud is making here therefore roughly coincides with the conventional but now outmoded distinction between the 'specific' and 'nonspecific' components of the forebrain.]

5 [This last point will be explained shortly (p. 342 below). – The absence of a protective screen towards the interior is pointed out in several later writings of Freud's: e.g. *Beyond the Pleasure Principle* (1920*g*), *RSE*, **18**, 28 f.]

6 [See footnote 1, p. 321 above.]

avoid the idea that there is an accumulation; and the intermittent character of their psychical effect necessitates the view that on their path of conduction to ψ they come up against resistances which are overcome only when there is an increase in quantity. They are therefore paths of conduction made up of multiple segments, having a number of contact barriers interpolated between them up to the ψ nucleus. Above a certain Q, however, they [the endogenous excitations] act as a stimulus continuously, and every increase of Q is perceived as an increase of the ψ stimulus. It follows, therefore, that there is a state in which the path of conduction has become permeable. Experience shows, further, that, after the ψ stimulus has been discharged, the path of conduction resumes its resistance once more.

A process of this kind is termed *summation*.[1] The ψ paths of conduction are filled by summation till they become permeable. It is evidently the smallness of the separate stimuli that permits summation. Summation is also proved to occur in the ϕ paths of conduction – for instance, in the case of the conduction of pain; it applies there only for small quantities. The lesser part played by summation on the ϕ side speaks in favour of the view that in fact we are there dealing with comparatively large Qs. Very small ones seem to be kept off by the operation of the nerve-ending apparatuses as a threshold [p. 337 f. above], while on the ψ side these [apparatuses] are absent and only small $Q\eta$s operate.

It is a very[2] noticeable fact that the ψ neurons of conduction are able to maintain a position between the characteristics of permeability and impermeability, since they recover their resistance almost completely in spite of the passage of $Q\eta$. This entirely contradicts the property we have assumed the ψ neurons to possess of being permanently facilitated by a current of $Q\eta$ [p. 324 above]. How is this contradiction to be explained?

By assuming that the restoration of resistance after a current has [317]
ceased is a general characteristic of contact barriers. There is not much difficulty, if so, in bringing this into harmony with the fact that ψ neurons are influenced [by the passage of quantity] in the direction of facilitation. We need only suppose that the facilitation which remains after the passage of Q consists, not in the lifting of every single

1 [This seems to be equivalent to the modern concept of 'graded potential'. Graded potentials are contrasted with 'action potentials' which are all-or-nothing events (see p. 322 *n.* 2 above). Summation in relation to endogenous excitation could perhaps also be linked with the modern concept of 'neuromodulation'. Peptides (hormone-like neuromodulators) serve many of the functional purposes Freud describes here.]

2 ['*Sehr*' in the MS. Omitted in *Anf.*, 401.]

resistance but in its reduction to a necessary remaining minimum. During the passage of Q the resistance is lifted; afterwards it is restored, but to various heights, in proportion to the Q that has passed through, so that the next time already a smaller Q will be able to pass through, and so on. When facilitation is most complete, a certain resistance remains which is equal for all contact barriers and which also requires the increase of Qs up to a certain threshold before they can pass. This resistance would be a constant. Accordingly, the fact that endogenous $Q\eta$ operates by summation signifies nothing more than that this $Q\eta$ is made up of very small amounts of excitation which are less than the constant. The endogenous path of conduction is therefore nevertheless[1] completely facilitated.

It follows from this, however, that the ψ contact barriers are in general higher than the barriers in the [endogenous] paths of conduction, so that a fresh accumulation of $Q\eta$ can occur in the nuclear neurons. [Cf. p. 348 below.] Once the path of conduction has been readjusted, no further limit is set to this accumulation. Here ψ is at the mercy of Q, and it is thus that in the interior of the system there arises the impulsion [*Antrieb*] which sustains all psychical activity. [Cf. pp. 340–1.] We know this power as the *will* – the derivative of the drives [*Triebe*].[2] [Cf. p. 362.]

[11] *The Experience of Satisfaction*

The filling of the nuclear neurons in ψ will have as its result an effort to discharge, an *urgency* which is released along the motor pathway. Experience[t] shows that here the first path to be taken is that leading to *internal change* (expression of the emotions, screaming, vascular innervation). But, as was explained at the beginning [p. 320 f. above], no such discharge can produce an unburdening result, since the endogenous stimulus continues to be received and the ψ tension is restored. The re-
[318] moval of the stimulus is only made possible here by an intervention which for the time being gets rid of the release of $Q\eta$ in the interior of the body; and this intervention calls for an alteration in the external world (supply of nourishment, proximity of the sexual object) which, as a *specific action*, can only be brought about in definite ways. At first, the human organism is incapable of bringing about the specific action. It takes place by *extraneous help*, when the attention of an experienced person is drawn to the child's state by discharge along the path of

1 ['*doch*' in the MS. Omitted in *Anf.*, 401.]

2 [This is one of the very rare appearances of the word '*Trieb*'[T] in Freud's early writings. See the Editors' Note to 'Drives and their Vicissitudes', *RSE*, **14**, 101.]

internal change.[1] In this way this path of discharge acquires a secondary function of the highest importance, that of *communication*, and the initial helplessness of human beings is the *primal source* of all *moral motives*. [Cf. p. 390 below.]

When the helpful person has performed the work of the specific action in the external world for the helpless one, the latter is in a position, by means of reflex [autonomic] contrivances, immediately to carry out in the interior of his body the activity necessary for removing the endogenous stimulus. The total event then constitutes an *experience of satisfaction*, which has the most radical results on the development of the individual's functions. For three things occur in the ψ system: (1) a lasting discharge is effected and so the urgency [*Drang*] which had produced unpleasure in ω is brought to an end; (2) a cathexis of one (or several) of the neurons which correspond to the perception of an object occurs in the pallium; and (3) at other points of the pallium information arrives of the discharge of the released reflex movement which follows upon the specific action. A facilitation is then formed between these cathexes and the nuclear neurons.[2]

The information of the reflex discharge comes about because every movement, through its subsidiary results, becomes the occasion for fresh sensory excitations (from the skin and muscles) which give rise to a *motor* [kinaesthetic] *image* in ψ.[3] The facilitation, however, is formed in a manner which allows of a deeper insight into the development of ψ. Hitherto we have learnt to know of ψ neurons being influenced through ϕ[4] and through endogenous paths of conduction; but the different ψ neurons were cut off from one another by contact barriers [319] with strong resistances. Now there is a basic law of *association by simultaneity*,[5] which operates in the case of pure ψ activity, of reproductive remembering, and which is the foundation of all links

1 [E.g. by the child's screaming.]

2 [These memory–motive linkages between an endogenous need (registered in the ψ nucleus) and an exogenous satisfier of that need (registered in the ψ pallium) is what justifies Freud's description of the forebrain as a 'sympathetic ganglion' (p. 327 above). This account of the 'experience of satisfaction' is repeated very closely in Chapter VII (C) of *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 505–6, and again, though more briefly, in the paper on the two principles of mental functioning (1911*b*), ibid., **12**, 216–17. Much of this is already foreshadowed in Freud's first paper on anxiety neurosis (1895*b*), ibid., **3**, 96 f., and in the no doubt earlier Draft E, p. 220 above.]

3 [See p. 336 *n*. 2 above.]

4 [So in the MS. *Anf*., 403, has '*ϕ-Neuronen*'.]

5 [Usually known under the more comprehensive name of 'association by contiguity'. This was subsequently renamed Hebb's law in the neuroscientific literature, after Hebb (1949) posited that 'neurons that fire together wire together'. This is precisely what Freud suggests here. Hebbian theory was very influential in the establishment of the concept of 'engrams' – the neuronal assemblages involved in enduring representations of any kind.]

between the ψ neurons. We find that consciousness – that is, the quantitative cathexis of a ψ neuron, α[1] – passes over to another, β, if α and β have at some time been simultaneously cathected from ϕ (or from elsewhere). Thus a contact barrier has been facilitated through the simultaneous cathexis α–β. It follows in the terms of our theory that a $Q\eta$ passes more easily from a neuron to a cathected neuron than to an uncathected one.[2] Thus the cathexis of the second neuron operates like the increased cathexis of the first one. *Once again, cathexis is here shown to be equivalent, as regards the passage of $Q\eta$, to facilitation*. [Cf. pp. 324–5 above.]

Here, therefore, we become acquainted with a second important factor in directing the course taken by the passage of $Q\eta$. A $Q\eta$ in neuron α will go not only in the direction of the barrier which is best facilitated, but also in the direction of the barrier which is cathected from the further side. The two factors may support each other or may in some cases operate against each other.

Thus, as a result of the experience of satisfaction, a facilitation comes about between two mnemic images[3] and the nuclear neurons which are cathected in the state of urgency. No doubt, along with the discharge of satisfaction the $Q\eta$ flows out of the mnemic images as well. Now, when the state of *urgency* or *wishing* reappears, the cathexis will also pass over on to the two memories and will activate them. Probably the mnemic image of the object will be the first to be affected by the *wishful activation*.

I do not doubt that in the first instance this wishful activation will produce the same thing as a perception – namely a *hallucination*. If reflex action is thereupon introduced, disappointment cannot fail to occur. [Cf. p. 365 below.]

1 [It is surprising to find consciousness thus defined, apparently without reference to ω.]

2 [This is referred to at several points below, e.g. on pp. 354 f. and 363. It reappears twenty years later in the metapsychological paper on dreams (1916–17*f* [1915]), *RSE*, **14**, 201 *n.* 2 and 208 *n.* 3, where it is named 'the principle of the insusceptibility to excitation of uncathected systems'. It is referred to again still later, in *Beyond the Pleasure Principle* (1920*g*), ibid., **18**, 29 f., and in the 'Mystic Writing-Pad' (1925*a*), ibid., **19**, 230 f. Cf. some observations in Breuer's theoretical chapter in *Studies on Hysteria* (1895*d*), ibid., **2**, 185–6.]

3 [By equating two neurons with two mnemic images here, Freud is following an established tradition in nineteenth-century neuropsychology, but one that he himself had severely criticized (Freud, 1891*b*; *NSW*, **4**). It is therefore noteworthy that his 'neurons' become increasingly figurative from here onwards, as he actually acknowledges on p. 353 below. The significant implication is that his account of the processes in question becomes less physiological and more functional, more metapsychological (see Editors' Introduction, p. 317 above). Thus, when Freud speaks in his later writings about the cathexis of an idea, he is harking back not to cathexes of neurons but rather of whole neuronal networks.]

[12] *The Experience of Pain*

Normally, ψ is exposed to Q from the endogenous paths of conduction, [320]
and abnormally, even though not yet pathologically, in cases where excessively large Qs break through the screening contrivances in ϕ – that is, in cases of *pain* [p. 331 f. above]. Pain gives rise in ψ (1) to a large rise in level, which is felt as unpleasure by ω [p. 336 f.],[1] (2) to an inclination to discharge, which can be modified in certain directions, and (3) to a facilitation between the latter [the inclination to discharge] and a mnemic image of the object which excites the pain. Moreover, there is no question but that pain has a peculiar *quality*, which makes itself felt along with the unpleasure.

If the mnemic image of the (hostile) object is freshly cathected in some way – for instance, by a fresh perception – a state arises which is not pain but which nevertheless has a resemblance to it. It includes *unpleasure* and the inclination to discharge which corresponds to the experience of pain. Since unpleasure signifies a rise in level, it must be asked where this $Q\eta$ comes from. In the actual experience of pain it was the irrupting external Q[2] that raised the ψ level. In the reproduction of the experience – in the *affect*[3] – the only additional Q is that which cathects the memory, and it is clear that this is in the nature of any other perception and cannot have as a result a general raising of $Q\eta$.

It only remains to assume, therefore, that owing to the cathexis of memories unpleasure is *released* from the interior of the body and freshly conveyed up. The mechanism of this release can only be pictured as follows. Just as there are motor neurons which, when they are filled to a certain amount, conduct $Q\eta$ into the muscles and accordingly discharge it, so there must be 'secretory' neurons which, when they are excited, cause the generation in the interior of the body of something which operates as a stimulus upon the endogenous paths of conduction to ψ – neurons which thus influence the production of endogenous $Q\eta$, and accordingly do not discharge $Q\eta$ but supply it in roundabout ways. We will call these motor [secretory] neurons 'key neurons'.[4] Evidently they are only excited when a certain level in ψ has been reached. As a result of [321]

1 [Cf. *Inhibitions, Symptoms and Anxiety* (1926*d*), *RSE*, **20**, 151–2.]

2 [It is of interest to note that in the MS. Freud first wrote '$Q\eta$' here, and afterwards crossed out the 'η'.]

3 [Cf. footnote 4, p. 346 below.]

4 [The 'key neuron' concept anticipates the neurosecretory function of hypothalamic neurons acting on the pituitary gland. For a discussion of Freud's adumbration of these hormone-releasing neurons, see Glick (1966). A reference to this view of motor and secretory innervation occurs in Chapter VI (H) of *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 418.]

the experience of pain the mnemic image of the hostile object has acquired an excellent facilitation to these key neurons, by virtue of which [facilitation] unpleasure is now released in the affect.[1]

Support is lent to this puzzling but indispensable hypothesis by what happens in the case of sexual release. At the same time a suspicion forces itself on us that in both instances the endogenous stimuli consist of *chemical products*, of which there may be a considerable number.[2] Since the release of unpleasure can be an extremely big one when there is quite a trivial cathexis of the hostile memory, we may conclude that pain leaves behind specially abundant facilitations. In this connection we may guess that facilitation depends entirely on the $Q\eta$ reached; so that the facilitating effect of $3Q\eta$ may be far superior to that of $3 \times Q\eta$.[3]

[13] *Affects and Wishful States*

The residues of the two kinds of experiences [of pain and of satisfaction]
[322] which we have been discussing are affects[4] and wishful states. These have in common the fact that they both involve a raising of $Q\eta$ tension in ψ – brought about in the case of an *affect* by sudden release and in that of a *wish* by summation. Both states are of the greatest importance for the passage [of quantity] in ψ, for they leave behind them motives for it which are of a compulsive kind. The wishful state results in a positive *attraction* towards the object wished for, or, more precisely, towards its mnemic image;[5] the experience of pain leads to a repulsion, a disinclination to

1 [These consequences of an experience of pain are described in *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 537.]

2 [Throughout his life Freud was interested in the possible chemical basis of the drives, and especially of the sexual drives. Some remarks on this can be found in the Editors' Note to the *Three Essays*, ibid., **7**, 112 and 191. Freud associated these ideas in particular with suggestions from Fliess, as is shown by a later passage in this work (p. 367 below). The earliest reference to the question in the Fliess papers appears in Draft D (p. 215 above). Cf. also an allusion in Letter 52 (p. 265 above). A very late mention of the subject occurs in the paper on 'Female Sexuality' (1931*b*), *RSE*, **21**, 228. In this last passage he refers back (only to dismiss it) to the theory of there being *several* sexual chemical substances.]

3 [Here '$3Q\eta$' stands for a quantity three times as large as $Q\eta$, and '$3 \times Q\eta$' stands for a quantity $Q\eta$ three times repeated. Freud seems to have been in some doubt as to how the former of these should be written. The MS. shows that in the present passage he began by writing '$3(Q\eta)$' and then corrected it to '$3Q\eta$'. In another passage (on p. 339 above) he had used the first of these forms, '$3(Q\eta)$', but in a still earlier passage, to which the present one in fact refers back (p. 326 above), he wrote '$Q:3\eta$'. The German editors of the *Anfänge* altered the earlier versions in different ways (*Anf.*, 386 and 399).]

4 [It might be thought from some passages here (see e.g. pp. 345 above and 360–1 below) that Freud was using the term 'affect' in relation to the reproduction only of disagreeable experiences. This is disproved entirely by a statement in connection with dreams on p. 365 below. Some discussion of Freud's use of the term can be found in *RSE*, **3**, 60–1.]

5 [Cf. *The Interpretation of Dreams* (1900*a*), ibid., **5**, 488.]

keeping the hostile mnemic image cathected. Here we have primary *wishful attraction* and primary *defence* [*Abwehr*T].[1]

Wishful attraction can easily be explained by the assumption that the cathexis of the friendly mnemic image[2] in a state of desire greatly exceeds in $Q\eta$ the cathexis which occurs when there is a mere perception, so that a particularly good facilitation leads from the ψ nucleus to the corresponding neuron of the pallium.

It is harder to explain primary *defence* or *repression* [*Verdrängung*]T – the fact that a hostile mnemic image is regularly[3] abandoned by its cathexis as soon as possible. Nevertheless, the explanation should lie in the fact that the primary experiences of pain were brought to an end by reflex defence. The emergence of another object in place of the hostile one was the signal for the fact that the experience of pain was at an end, and the ψ system, taught *biologically*, seeks to reproduce the state in ψ which marked the cessation of the pain. With the expression *taught biologically* we have introduced a new basis of explanation, which should have independent validity, even though it does not exclude, but rather calls for, a recourse to mechanical principles (quantitative factors).[4] In the instance before us it may easily be the increase of $Q\eta$, invariably occurring with the cathexis of a hostile memory, which forces an increased activity of discharge and thus a flowing away from the memory as well.

[14] *Introduction of the 'Ego'*

In fact, however, with the hypotheses of '*wishful attraction*' and of the inclination to *repression* we have already touched on a state of ψ which has not yet been discussed. For these two processes indicate that an or- [323]
ganization has been formed in ψ whose presence interferes with passages [of quantity] which on the first occasion occurred in a particular way [i.e. accompanied by satisfaction or pain]. This organization is called the 'ego' [*Ich*]T. It can easily be depicted if we consider that the regularly repeated reception of endogenous $Q\eta$ in certain neurons (of

1 [This description of the mechanical action of the pleasure principle (p. 336 f. above) on the mnemic images lays the foundation for the primary-process concept (p. 349 ff. below) and the reality principle (p. 351 f. below).]

2 [In the MS.: '*die Besetzg des freundlichen Er*[*innerungsbildes*]'. *Anf.*, 406, reads: '*der . . . Erinnerung*' ('of the memory'), having misread the gender of the definite article.]

3 ['*stets*' in the MS. Omitted in *Anf.*, 406.]

4 [The biological basis of explanation was actually introduced on p. 326 already. Cf. footnote 1, p. 330 above.]

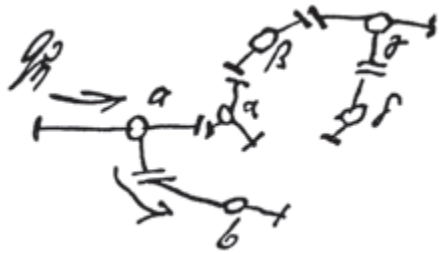
the nucleus) and the facilitating effect proceeding thence will produce a group of neurons which is constantly cathected [pp. 341 f. above and 393 below] and thus corresponds to the *vehicle of the store* required by the secondary function [p. 321]. Thus the ego is to be defined as the totality of the ψ cathexes, at the given time, in which a permanent component is distinguished from a changing one [p. 353 f.]. It is easy to see that the facilitations between ψ neurons are a part of the ego's possessions, as representing possibilities, if the ego is altered, for determining its extent in the next few moments.[1]

While it must be the endeavour of this ego to give off its cathexes by the method of satisfaction, this cannot happen in any other way than by its influencing the repetition of experiences of pain and of affects, and by the following method, which is described generally as *inhibition* [*Hemmung*][T].

A $Q\eta$ which breaks into a neuron from anywhere will proceed in the direction of the contact barrier with the largest facilitation and will set up a current in that direction. To put this more accurately: the $Q\eta$ current will divide up in the direction of the various contact barriers in inverse ratio to their resistance [see p. 325 *n*. 1 above]; and, in that case, where a contact barrier is impinged upon by a quotient which is inferior to its [the contact barrier's] resistance, nothing will in practice pass through there. This relation may easily turn out differently in the case of each $Q\eta$ in the neuron, for quotients may then arise which are superior to the threshold at other contact barriers as well. Thus the course taken is dependent on $Q\eta$ and the relation of the facilitations. We have, however, come to know the third powerful factor [p. 343 f. above]. If an adjoining neuron is simultaneously cathected, this acts like a temporary facilitation of the contact barrier lying between the two, and modifies the course [of the current], which would otherwise have been directed towards the one facilitated contact barrier. A *side cathexis* thus acts as *an inhibition of the course of* $Q\eta$.[2] Let us picture the ego as a network of cathected neurons well facilitated in relation to one another, thus [see Fig. 14]:

1 [The mechanical properties of the 'constantly cathected' ego neurons, and indeed their anatomical location in relation to the ψ nucleus, suggest that they are equivalent to what is today called the 'default mode network' (see Carhart-Harris & Friston, 2010).]

2 [Much has been made in the secondary literature about the fact that Freud did not invoke central inhibitory neurons but instead assumed that all neuronal transmission is excitatory, and that inhibition (hyperpolarization) therefore arises indirectly from interactions between excitatory (depolarizing) neurons. In fact, although the phenomenon of central inhibition was well recognized by 1895, its mechanism was not. Some physiologists described inhibition as a local, positive function of specific neurons and others described it as a general, negative function of interactive neuronal processes. Causal speculation was still rife at this time and Freud's proposals were not atypical. See Smith (1992, 94, 213).]



[Fig. 14]

If we suppose that a $Q\eta$ enters a neuron *a* from outside (ϕ), then, if it were uninfluenced, it would pass to neuron *b*; but it is so much influenced by the side cathexis *a*–α that it gives off only a quotient to *b* and may even perhaps not reach *b* at all. Therefore, if an ego exists, it must [324] *inhibit* psychical primary processes.

Inhibition of this kind is, however, a decided advantage to ψ. Let us suppose that *a* is a[1] hostile mnemic image and *b* a key neuron to unpleasure [p. 345 above]. Then, if *a* is awakened, primarily unpleasure would be released, which would perhaps be pointless and is so in any case [if released] to its full amount. With an inhibitory action from α the release of unpleasure will turn out very slight and the nervous system will be spared the development and discharge of *Q* without any other damage. It is easy now to imagine how, with the help of a mechanism which draws the ego's *attention*[2] to the imminent fresh cathexis of the hostile mnemic image, the ego can succeed in inhibiting the passage [of quantity] from a mnemic image to a release of unpleasure by a copious side cathexis which can be strengthened according to need. Indeed, if we suppose that the original $Q\eta$ release of unpleasure is taken up by the ego itself, we shall have in it itself the source of the expenditure which is required by the inhibiting side cathexis from the ego. In that case, the stronger the unpleasure, the stronger will be the primary defence.

[15] *Primary and Secondary Process*[3] *in* ψ

It follows from what has developed so far, that the ego in ψ, which we can treat as regards its trends like the nervous system as a whole,[4] will,

1 [In the MS.: '*ein*'; *Anf.*, 408, reads: '*eine . . . Erinnerung*'.]

2 ['Attention' is discussed on p. 384 ff. below.]

3 [This fundamental distinction makes its first appearance at the end of this section. Some discussion of it can be found in Appendix C, p. 417 below.]

4 ['*Gesamtnervensystem*', written out in the MS. (Cf. p. 320 *n.* 3 above.)]

when the processes in ψ are uninfluenced, be made helpless and suffer injury under two conditions.

[325] That is to say, this will happen in the first place if, while it is in a *wishful state*, it newly cathects the memory of an object and then sets discharge in action; in that case satisfaction must fail to occur, because the object is not *real* but is present only as an imaginary *idea* [*Phantasievorstellung*][T]. ψ is not in a position, to begin with, to make this distinction, since it can only work on the basis of the sequence of analogous states between its neurons.[1] Thus it requires a criterion from elsewhere in order to distinguish between *perception* and *idea*.

On the other hand, ψ is in need of an indication that will draw its attention to the recathexis of a hostile mnemic image and enable it to obviate, by means of side cathexis, the consequent release of unpleasure. If ψ is able to put this inhibition into operation soon enough, the release of unpleasure, and at the same time the defence, will be slight; otherwise there will be immense unpleasure and excessive primary defence.

Both wishful cathexis and release of unpleasure, where the memory in question is cathected anew, can be biologically detrimental. This is true of a wishful cathexis whenever it exceeds a certain amount and so acts as an enticement to discharge; and it is true of a release of unpleasure, at least whenever the cathexis of the hostile mnemic image results not from the external world but from ψ itself (by association). Here once again, then, it is a question of an indication to distinguish between a perception and a memory (idea).[2]

It is probably the ω neurons which furnish this indication: the *indication of reality*.[3] In the case of every external perception a qualitative excitation occurs in ω [pp. 333–4 above], which in the first instance, however, has no significance for ψ. It must be added that the ω excitation leads to ω discharge, and information of this, as of every discharge [p. 343], reaches ψ.[4] *The information of the discharge from ω is thus the indication of quality or of reality for ψ.*

1 [I.e. the sequence between a wish and a hallucination, as described in the later part of Section 11 (p. 344 above).]

2 [In the MS.: '*W (Wahrnehmg) von Er (Vorstellg) zu unterscheiden*.' – The present discussion is perhaps Freud's earliest attempt to grapple with the problem of 'reality-testing' (of how we decide whether or not a thing is real), to which he returns at several points below and which occupied him constantly over the years. See Appendix C, p. 419 below.]

3 ['*Realitätszeichen*.' The almost identical term, '*Kennzeichen der Realität*', appears in the metapsychological paper on dreams (*1916–17f* [1915]), *RSE*, **14**, 207.]

4 [The sense here and elsewhere (e.g. p. 336 above) seems to indicate that ω discharge is a *motor* process. This answers the rhetorical question posed in footnote 4, p. 334 above: the ω neurons are located at the motor end of the apparatus – therefore (like ϕ) at the periphery of the ψ pallium (and 'subpallium', cf. p. 340 *n*. 4 above; see also p. 395 below). This is accordingly the location

If the wished-for object is abundantly cathected, so that it is activated in a hallucinatory manner, the same indication of discharge or of reality follows too as in the case of external perception. In this instance the criterion fails. But if the wishful cathexis takes place subject to *inhibition*, [326] as becomes possible when there is a cathected ego, a quantitative instance can be imagined in which the wishful cathexis, not being intense enough, produces no *indication of quality*, whereas the external perception would produce one. In this instance, therefore, the criterion would retain its value. For the difference is that the *indication of quality* follows, if it comes from outside, whatever the intensity of the cathexis, whereas, if it comes from ψ, it does so only when there are large intensities. It is accordingly *inhibition by the ego which makes possible a criterion for distinguishing between perception and memory*.[1] Biological experience will then teach that discharge is not to be initiated till the *indication of reality* has arrived, and that with this in view the cathexis of the desired memories is not to be carried beyond a certain amount.[2]

On the other hand, the excitation of the ω neurons can also serve to protect the ψ system in the second case: that is, by drawing the attention of ψ to the fact of a perception being present or absent. For this purpose it must be assumed that the ω neurons are originally linked anatomically with the paths of conduction from the various sense organs[3] and that they [the ω neurons] direct their discharge back to the motor apparatuses belonging to those same sense organs. In that case the information of the latter discharge (the information of *reflex attention*) will act to ψ biologically as a signal[4] to send out a quantity of cathexis in the same directions.

assigned to the *Cs.* system in *The Interpretation of Dreams* (1900*a*) and it is also consistent with Freud's subsequent (1916–17*f* [1915]) conflation of the two (here adjacent) systems. In the intervening period, in the January 1, 1896 revision of the 'Project' (Appendix B below), Freud located ω between ϕ and ψ at the perceptual end of the apparatus. The whole matter seems to pivot on the fact that afferent and efferent motor neurons are anatomically adjacent in the cerebral cortex, where they form an integrated functional unit (see pp. 388 and 411 below). However, it may be recalled that the 'key neurons' too are motor neurons, directed towards the interior of the body. This introduced further complications relating to the qualitative characteristics of endogenous stimuli (felt in the pleasure–unpleasure series; see Editors' Introduction, p. 313 *n.* 2 above).]

1 [I.e. it suppresses hallucination.]

2 [In modern neuropsychology and control theory, this would be described as an *executive* function. It is common practice in computer programming to make all (relatively independent) subroutines end by transferring control to an executive routine, which then 'decides' what to do next. In this sense the subroutines are subordinate to the executive routine. (See Pribram & Gill, 1976, 78 ff.) This executive function underpins all the cognitive operations described in the following sections and in almost the whole of Part III below. See, in particular, Editors' footnote 1, p. 418.]

3 [This anticipates Freud's January 1, 1896 revision of the anatomical position of the ω system. See Appendix B below.]

4 [This is perhaps a first hint at the much later theory of anxiety as a signal. See the Editors' Introduction to *Inhibitions, Symptoms and Anxiety* (1926*d*), *RSE*, **20**, 73 f. Cf. also pp. 382, 383 and 406 below.]

So then: if there is inhibition by a cathected ego, the indications of ω discharge become quite generally *indications of reality*, which ψ learns, biologically, to make use of. If, when an *indication of reality* of this kind emerges, the ego is in a state of wishful tension, it will allow discharge towards the specific action to follow [pp. 342–3 above]. If an increase of unpleasure coincides with the *indication of reality*, then ψ will, by means of a side cathexis of suitable magnitude, institute a defence of normal magnitude at the point indicated. If neither of these is the case,[1] the cathexis will be allowed to proceed unhindered according to the circumstances of the facilitations.[2] Wishful cathexis to the point of hallucination [and] complete generation of unpleasure which involves a complete ex-
[327] penditure of defence are described by us as *psychical primary processes*; by contrast, those processes which are only made possible by a good cathexis of the ego, and which represent a moderation of the foregoing, are described as *psychical secondary processes*. It will be seen that the necessary precondition of the latter is a correct employment of the *indications of reality*, which is only possible when there is inhibition by the ego.

[16] *Cognition and Reproductive Thought*[3]

We have brought forward the hypothesis that, during the process of wishing, inhibition by the ego brings about a moderated cathexis of the object wished for, which allows it to be cognized as not real; and we may

1 [I.e. if neither a wishful state nor an increase of unpleasure is present when the indication of reality is received.]

2 [The relative distribution of quantities and contact barriers (p. 348 above).]

3 [In the MS. the title of this section reads '*Das Erkennen u*[*nd*] *reproduzirende Denken*'. *Anf.*, 411, alters this to '*Das erkennende und reproduzierende Denken*' ('Cognitive and Reproductive Thought'). – Sections 16, 17 and 18 of Part I, as well as almost the whole of Part III, are concerned with the classification and analysis of processes of thought. In the discussion in Part I the main distinction drawn is between, on the one hand, the very closely related and possibly identical concepts of 'cognition' and 'judgement' and, on the other hand, that of 'reproductive thought', which covers such functions as remembering, wishing, desiring and expecting. In Part III the same points are reviewed, but with much deeper penetration. 'Reproductive thought' disappears almost completely from view, and fresh terms are introduced, such as 'practical thought', 'observant thought', 'theoretical thought' and 'critical thought'. It will be found that these very difficult discussions become a little easier to follow when *both* those in Part III and Part I are taken into account, since they often cover the same ground and throw light on each other. – '*Erkennen*', here translated 'cognition', literally means 're-cognition' (i.e. comprehension). The English word, as used in modern 'cognitive' science, obscures the fact that the processes under study involve representations originally derived from external perception. Similar considerations apply to the relationship between 'recognition' and '*gnosis*' (cf. Freud, 1891*b*; *NSW*, **4**, Chapter VI). It may be remarked that it is precisely this derivation of the term (and the underlying neural processes) that prompted the establishment of modern 'affective neuroscience' as a separate discipline from cognitive neuroscience (see Panksepp, 1998).]

now proceed with the analysis of this process. Several possibilities may occur. In the first case: simultaneously with the wishful cathexis of the mnemic image, the perception of it is present. If so, the two cathexes coincide – which cannot be made use of biologically – but, in addition, the indication of reality arises from ω, after which, as experience shows [*erfahrungsgemäss*], the discharge is successful [pp. 351–2 above]. This case is easily dealt with. In the second case:[1] the wishful cathexis is present and along with it a perception which does not tally with it wholly but only in part. For the time has come to remember that perceptual cathexes are never cathexes of single neurons but always of complexes. So far we have neglected this feature; it is time to take it into account.[2] Let us suppose that, quite generally, the wishful cathexis relates to neuron $a+$ neuron b, and the perceptual cathexis to neuron $a+c$. Since [328] this will be the commoner case, commoner than that of identity, it calls for more exact consideration. Biological experience will teach here once again [p. 351 above] that it is unsafe to initiate discharge if the indications of reality do not confirm the whole complex but only a part of it. A way is now found, however, of completing the similarity into an identity. The perceptual complex, if it is compared with other perceptual complexes, can be dissected into a component portion, neuron *a*, which on the whole remains the same, and a second component portion, neuron *b*, which for the most part varies. Language will later apply the term *judgement* to this dissection and will discover the resemblance which in fact exists between the nucleus of the ego and the constant perceptual component [on the one hand] and between the changing cathexes in the pallium [pp. 340 and 347 f. above] and the inconstant component [on the other]; it [language] will call neuron *a* the *thing* and neuron *b* its activity or attribute – in short, its *predicate*. [Cf. pp. 356–7, 390 and 407 below.]

Thus *judging* is a ψ process which is only made possible by inhibition by the ego and which is evoked by the dissimilarity between the *wishful cathexis* of a memory and a perceptual cathexis that is similar to it. It can be inferred from this that coincidence between the two cathexes becomes a biological signal for ending the act of thought and for allowing discharge to begin. Their non-coincidence gives the impetus for

1 [A third case is discussed on p. 355 ff. below.]

2 [Cf. footnote 3, p. 344 above. The term 'complexes' as used here is equivalent to what are today called 'engrams' or 'neuronal networks' (see p. 343 *n.* 5 above). The number of neurons that would be involved in the account that follows would have to be in the magnitude of many thousands. The account therefore becomes functional rather than truly mechanical.]

the activity of thought, which is terminated once more with their coincidence.[1]

The process can be analysed further. If neuron *a* coincides [in the two cathexes] but neuron *c* is perceived instead of neuron *b*, then the activity of the ego follows the connections of this neuron *c* and, by means of a current[2] of *Qη* along these connections, causes new cathexes to emerge until access is found to the missing neuron *b*. As a rule, the image of a movement [a motor image] arises which is interpolated between neuron *c* and neuron *b*; and, when this image is freshly activated through a movement carried out really, the perception of neuron *b*, and at the same time the identity that is being sought,[3] are established. Let us suppose, for instance, that the mnemic image wished for [by a child] is the image of the
[329] mother's breast and a front view of its nipple, and that the first perception is a side view of the same object, without the nipple. In the child's memory there is an experience, made by chance in the course of sucking, that with a particular head movement the front image turns into the side image. The side image which is now seen leads to the [image of the] head movement; an experiment shows that its counterpart must be carried out, and the perception of the front view is achieved.[4]

There is not much judgement about this as yet; but it is an example of the possibility of arriving, by a reproduction of cathexes, at an action which is already one of the accidental offshoots of the specific action.

There is no doubt that it is *Qη* from the cathected ego which underlies this travelling [*Wanderungen*] along the facilitated neurons and that this travelling is dominated not by the facilitation but by an aim. What is this aim and how is it reached?

The aim is to go back to the missing neuron *b* and to release the sensation of identity – that is, the moment at which only neuron *b* is cathected, at which the travelling cathexis debouches into neuron *b*. [Cf. pp. 357 f. and 402 below.] It is reached by means of an experimental displacement of *Qη* along every pathway, and it is clear that for this purpose sometimes a larger and sometimes a smaller expenditure of side cathexis is necessary, according to whether one can make use of the

1 [Cf. the similar account of judgement in 'Negation' (1925*h*), *RSE*, **19**, 240. The present account also presages Freud's metapsychology of thought in general, in terms of which thought (as 'experimental action') is interposed between a drive demand and the action that satisfies it (cf. Freud, 1911*b*; ibid., **12**, 217 f.; and 1933*a*; ibid., **22**, 67, 79).]

2 [Freud originally wrote '*Besetz*[*un*]*g*' ('cathexis') here, but crossed it out and put '*Ström*[*un*]*g*' ('current') instead.]

3 [See footnote 1, p. 358 below.]

4 [The hungry baby is used as an illustration in similar conditions on pp. 321 and 342–3 above, but also in *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 505 f.]

facilitations that are present or whether one has to work against them. The struggle between the established facilitations and the changing cathexes is characteristic of the secondary process of reproductive thought, in contrast to the primary sequence of [undirected] association.

What is it that directs this travelling? The fact that the wishful idea of the memory[1] [i.e. of neuron *b*] is kept cathected while the association is followed from neuron *c*. As we know [p. 343 f. above], a cathexis like this of neuron *b* makes all its possible connections themselves more facilitated and accessible.

In the course of this travelling it may happen that the *Qη* comes upon [330]
a memory which is connected with an experience of pain and thus gives occasion for a release of unpleasure. Since this is a sure sign that neuron *b* is not to be reached along that pathway, the current is at once diverted from the cathexis in question. Unpleasurable paths, however, retain their great value in directing the current of reproduction.

[17] *Remembering and Judging*

Thus reproductive thought has a practical aim and a biologically established end – namely, to lead a *Qη*, which is travelling from the superfluous [unwanted] perception, back to the cathexis of the missing neuron. With this, identity[2] and a right to discharge are achieved, if in addition the indication of reality appears from neuron *b*. The process can, however, make itself independent of this latter aim and strive only for identity. If so, we have before us a pure act of thought, though this can in any case be put to practical use later. Here, moreover, the cathected ego is behaving in exactly the same way.

We now come to a third possibility that can arise in a wishful state:[3] when, that is, there is a wishful cathexis and a perception emerges which does not coincide in any way with the wished-for mnemic image (mnem.+).[4] Thereupon there arises an interest for *cognizing* [*zu erkennen*] this perceptual image, so that it may perhaps after all be

1 [The text is uncertain here. *Anf*., 414, reads: '*die Wunschvorstellungs-Erinnerung*', which makes poor sense and is certainly not given by the MS. The first word begins with '*Wunsch*' and ends with '*stellg*', but what lies between is doubtful; the second word is quite clearly '*Er*[*innerung*]'. What one would expect might possibly be '*die Wunschvorstellung der Erinnerung*' (as conjectured in the translation above and as the *GW* edition has it); but this again is certainly not given by the MS. The general sense is, in any case, clear. Cf. the similar passage on p. 400 below.]

2 [Cf. footnote 1, p. 358 below.]

3 [For the first two, see pp. 352–3 above.]

4 [The 'plus' sign seems to indicate 'wished for'. It appears again later, on p. 400 f. below.]

possible to find a pathway from it to mnem.+. It is to be assumed that, with this aim in view, the perceptual image is again hypercathected[I] from the ego, as happened in the previous case with only a component part of it, neuron *c*. If the perceptual image is not absolutely new, it will now *recall* and *revive* a mnemic perceptual image with which it coincides at
[331] least partly.[2] The previous process of thought is now repeated in connection with this mnemic image, though to some extent without the *aim* which was afforded previously[3] by the cathected wishful idea [p. 354 f. above].

Insofar as the cathexes coincide, they give no occasion for activity of thought. On the other hand, the non-coinciding portions 'arouse interest' and can give occasion for activity of thought in two ways. The current is either directed on to the *aroused* memories and sets an aimless activity of memory at work, which is thus moved by differences and not by similarities, or it [the current] remains in the components [of the perception] which have newly emerged and in that case exhibits an equally aimless *activity of judging*.[4]

Let us suppose that the object which furnishes the perception resembles the subject – a *fellow human being*. If so, the theoretical interest [taken in it] is also explained by the fact that an object *like this* was simultaneously the [subject's] first satisfying object and further his first hostile object, as well as his sole helping power [*Macht*][T]. For this reason it is in relation to a fellow human being that a human being learns to cognize. Then the perceptual complexes proceeding from this fellow human being will in part be new and non-comparable – his *features*, for instance, in the visual sphere; but other visual perceptions – e.g. those of the movements of his hands – will coincide in the subject with memories of quite similar visual impressions of his own, of his own body, [memories] which are associated with memories of movements experienced [*erlebten*][5] by himself. Other perceptions of the object too – if, for

1 [I.e. receives an extra amount of cathexis. A list of some late occurrences of the term is given in a footnote to Lecture XXIII of the *Introductory Lectures* (1916–17*a*), *RSE*, **16**, 330 *n*. 2. See also Appendix C, p. 418 *n*. 2 below.]

2 [In the last sentence, *Anf*., 415, systematically alters the gender of '*W*' from the neuter '*Wahrnehmungsbild*' ('perceptual image') (of the MS.) to the feminine '*Wahrnehmung*' ('perception'), and, in the sentence before, expands '*W*' into '*die Wahrnehmung*' instead of into the more probable '*Wahrnehmungsbild*'. The *GW* edition follows this latter transcription.]

3 [There is a second '*vorhin*' in the MS. at this point in the sentence. Omitted in *Anf*., 415.]

4 [The italicizing in this paragraph follows the underlining in the MS. One would have expected 'activity of memory' to be stressed rather than 'aroused', in contrast to 'activity of judging'.]

5 [The distinction between lived (inner) and empirical (outer) 'experience' ('*Erlebnis*' and '*Erfahrung*'), which is lost in translation, is especially important in these sections. The German is therefore given in square brackets wherever the meaning is ambiguous.]

instance, he screams – will awaken the memory of his [the subject's] own screaming and at the same time of his own experiences of pain. Thus the complex of the fellow human being falls apart into two components, of which one makes an impression by its constant structure and stays together as a *thing*, while the other can be *understood* by the activity of memory – that is, can be traced back to information from [the subject's] own body.[1] This dissection of a perceptual complex is described as *cognizing* it; it involves a *judgement* and when this last aim has been attained it comes to an end. Judgement, as will be seen, is not a primary function,[2] [332] but presupposes the cathexis from the ego of the disparate [non-comparable] portions [of the perception]; in the first instance it has no practical purpose and it seems that during the process of judging the cathexis of the disparate components is discharged, for this would explain why activities, 'predicates' [p. 353 above], are separated from the subject complex by a comparatively loose pathway.[3]

It would be possible from this point to enter deeply into the analysis of the act of judgement; but this would divert us from our topic. Let us content ourselves with bearing firmly in mind that it is the original interest in establishing the situation of satisfaction that has led in the one case to *reproductive consideration*[4] and in the other to *judging*, as a method of proceeding from the perceptual situation that is given in reality to the situation that is wished for.[5] The necessary precondition for this remains that the ψ processes should not pursue their passage uninhibited but in conjunction with an active ego. The eminently practical sense of all thought activity would in this way seem to be demonstrated.

[18] *Thought and Reality*

The aim and end of all thought processes is thus to bring about a *state of identity*, the conveying of a cathexis $Q\eta$, emanating from outside, into a

1 [As the editors of the *Anfänge* point out, a distant approach to this idea may be seen in a passage in Chapter VII of Freud's book on *Jokes* (1905*c*), in which he discusses 'ideational mimetics', *RSE*, **8**, 167 f. The concept of ideational mimetics is there linked to the bigger concept of 'empathy' with which Freud deals here for the first time. In modern neuroscience, empathy is frequently linked with the concept of 'mirror neurons' which may perhaps be equated with what Freud here describes as 'information from [the subject's] own body'.]

2 [In the MS.: '*Primärf*'. '*Primärfunktion*' in *Anf.*, 416. – This in no way conflicts with the distinction drawn in the next section between primary and secondary judging.]

3 [This is made more intelligible later: see pp. 390 and 407 below.]

4 ['*reproduzierendes Nachdenken*.' Everywhere else here the word used is '*Denken*'. – The alternative cases recall those mentioned on p. 356 above of 'an aimless activity of memory' and 'an aimless activity of judging'. – See also p. 382 *n.* 3 below.]

5 [Cf. footnote 1, p. 354 above.]

neuron cathected from the ego.[1] *Cognitive* or *judging* thought seeks an identity with a bodily cathexis, *reproductive* thought seeks it with a psychical cathexis of one's own[2] (an experience [*Erlebnis*] of one's own).
[333] Judging thought operates in advance of reproductive thought by furnishing it with ready-made facilitations for further associative travelling. If after the conclusion of the act of thought the indication of reality reaches the perception,[3] then a *judgement of reality*, *belief*, has been achieved and the aim of the whole activity attained.

As regards judging, there is further to be remarked that its basis is obviously the presence of bodily experiences, sensations and motor images of one's own. So long as these are absent, the variable[4] portion [p. 353 above] of the perceptual complex remains ununderstood – that is, it can be reproduced but does not point a direction for further paths of thought. Thus, for instance, and this will become important in what follows [in Part II], no sexual experiences [*Erfahrungen*] produce any effect so long as the subject is ignorant of all sexual feeling – in general, that is, till the beginning of puberty.

Primary judging seems to presuppose a lesser influence by the cathected ego than do reproductive acts of thought. In this [in primary judging] it is a matter of pursuing an association which is due to partial coincidence [between the wishful and perceptual cathexes] – an association to which no modification is applied.[5] And indeed, cases also occur in which the associative process of judging is carried out with a full [amount of] quantity. The perception may correspond to an object nucleus + a motor image. While one is perceiving the perception, one copies the movement oneself – that is, one innervates so strongly the motor image of one's own which is aroused towards coinciding [with the perception], that the movement is carried out. Hence one can speak of a perception having an *imitation value*.[6] Or the perception may arouse the mnemic image of a sensation of pain of one's own, so that one feels the corresponding

1 [Cf. p. 354 above. A similar line of thought is developed in Chapter VII (C) and (E) of *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 506–7 and 538–9, where Freud speaks of 'perceptual identity' and 'thought identity'.]

2 ['*Eigenen*' in the MS. Omitted in *Anf.*, 417. For this rather obscure sentence, cf. the discussion of cognizing on p. 357 above.]

3 [*Anf.*, 417, adds the word '*hinzu*' ('as well') (not in the MS.).]

4 ['*Variable*' in the MS. *Anf.*, 417, has, inexplicably, '*verarbeitende*' ('modifying').]

5 [This is incorrectly printed in *Anf.*, 417, which has a comma at this point, followed by a '*so*' with a lower-case initial. Actually the MS. shows a plain full stop, and the next word begins with an upper-case 'S' – a letter which in the Gothic hand cannot possibly be confused with a lower-case 's'. The emendation of this very difficult passage was perhaps made because the sentence ending here does not read grammatically in the original.]

6 [Cf. pp. 390–1 below, and also footnote 1, p. 357 above.]

unpleasure and repeats the appropriate defensive movement. Here we have the *sympathy value* [*Mitleidswert*] of a perception.

In these two cases we must no doubt see the *primary process* in respect of judging,[1] and we may assume that all secondary judging has come about through a mitigation of these purely associative processes. Thus judging, which is later a means for the *cognition* of an object that may possibly be of practical importance, is originally an associative process between cathexes coming from outside and arising from one's own body – an *identification of information or cathexes from ϕ and from within*.[2] It is perhaps not wrong to suspect that it [judging] at the same time represents a method by which Qs coming from ϕ can be transmitted and discharged. What we call *things* are residues which evade being judged. [334]

The example of judgement gives us for the first time a hint of the difference in their quantitative characteristic which is to be discovered between thought and the primary process. It is justifiable to suppose that during *thought* a slight current of motor innervation passes from ψ – only, of course, if during the process a motor or key neuron [p. 345 above] has been innervated. Nevertheless, it would be wrong to take this discharge for the process of thought itself, of which it is only an unintended subsidiary effect.[3] The *process of thought* consists in the cathexis of ψ neurons, accompanied by a change, brought about by side cathexis from the ego, in what is imposed by the facilitations. It is intelligible from the mechanical point of view[4] that here only a part of the $Q\eta$ is able to follow the facilitations and that the magnitude of this part is constantly regulated by the cathexes. But it is also clear that at the same time enough $Q\eta$ is economized by this to make the reproduction profitable as a whole. Otherwise, *all* the $Q\eta$, which is finally needed for discharge, would be given off at the points of motor outlet during the course of its passage. *Thus the secondary process is a repetition of the original ψ passage* [of quantity], *at a lower level, with smaller quantities*.[5]

1 [I.e. in the cases of imitation and of sympathy.]

2 [It is of theoretical importance to note that the cathexes 'from within' are not only kinaesthetic sensations. The implication is that the ψ information or cathexes arising from one's own body in the empathic processes described here derive partly from endogenous sources – i.e. that they could include affects. (See Editors' Introduction, p. 313 *n*. 2 above.)]

3 [This introduces the essential characteristics of what will later become the system *Pcs*. in Freud's metapsychological writings. It is noteworthy that *Pcs*. is located with *Cs*. at the motor end of the apparatus (see Freud, 1900*a*).]

4 [Cf. footnote 1, p. 330 above.]

5 [This theory of the economics of thought is another basic idea running through all Freud's later writings. See the long list of references in a footnote to Lecture XXXII of the *New Introductory Lectures* (1933*a*), *RSE*, **22**, 79 *n*.]

'With $Q\eta$s even smaller', it will be objected, 'than those that ordinarily pass through in ψ neurons? How can it be arranged that such small $Q\eta$s shall have open to them pathways which, after all, are only traversable by larger ones than ψ as a rule receives?' The only possible reply is that this must be a mechanical result of the side cathexes. We must conclude that matters stand in such a way that when there is a side cathexis small
[335] $Q\eta$s flow through facilitations which would ordinarily be traversed only by large ones. The side cathexis as it were *binds* a quota of the $Q\eta$ flowing through the neuron.[1]

There is a further condition that thought must satisfy. It must make no essential change in the facilitations created by the primary processes; otherwise, indeed, it would falsify the traces of reality. Of this condition it is enough to remark that facilitation is probably the result of a single [passage of a] major quantity and that cathexis, though very powerful at the moment, nevertheless does not leave any comparable lasting effect behind it. The small Qs that pass during thought cannot in general prevail against the facilitations.

There is no doubt, however, that the process of thought does leave lasting traces behind it, since a second thinking, a rethinking,[2] calls for so much less expenditure [of energy] than a first. In order that reality shall not be falsified, therefore, special traces are needed, signs of the processes of thought, constituting a thought memory which it is not yet possible to shape. We shall hear later by what means the traces of thought processes are distinguished from those of reality.[3]

[19] *Primary Processes – Sleep and Dreams*[4]

The question now arises as to what, then, the quantitative means may be by which the ψ *primary process* is sustained. In the case of an *experience of pain* it is evidently the irrupting Q from outside; in the case of an *affect* it is the endogenous Q[5] released by facilitation. In the case of the secondary process of *reproductive thought* a greater or lesser $Q\eta$ can

1 [The concept of 'binding' and this whole subject is more fully discussed in Part III, p. 392 ff. below. See also Appendix C, pp. 417–18 below.]

2 ['*Überdenken*.' Cf. pp. 324 above and 402–3 below.]

3 [See below in Part III, particularly pp. 389–90 and 402–3.]

4 [The later part of this section and the two following ones contain much that anticipates *The Interpretation of Dreams* (1900*a*). Editorial remarks on the modern neuroscientific equivalents of the processes described are reserved for there (*RSE*, **4** and **5**).]

5 ['*Qend*' in the MS. *Anf.*, 419, simply reads '*Quantität*', having apparently failed to recognize the '*end*'. Cf. also p. 345 above.]

obviously be transferred to neuron *c* from the ego [p. 354 above], and this [$Q\eta$] may be described as *thought interest*,[1] and be proportionate to the *affective interest* where that may have developed. The question is only whether there are ψ processes of a primary nature for which the $Q\eta$ supplied from ϕ is sufficient or whether the ϕ cathexis of a perception is automatically supplemented by a ψ contribution (attention) which alone [336]
makes a ψ process possible. [See p. 362 below.] This question must remain an open one, though it may perhaps be decided if it is specially applied to [some] psychological facts.

It is an important fact that ψ *primary processes*, such as have been biologically suppressed in the course of ψ development, are daily presented to us during sleep. A second fact of the same importance is that the pathological mechanisms which are revealed in the psychoneuroses by the most careful analysis have the greatest similarity to dream processes. The most important conclusions follow from this comparison, which will be enlarged on later [p. 366].[2]

First, the fact of sleep must be brought into our theory. The *essential precondition* for sleep may be clearly recognized in children. Children sleep so long as they are not tormented by any [physical] need or external stimulus (hunger and cold from wetting). They go to sleep after being satisfied (at the breast). Adults, too, fall asleep easily *post coenam et coitum*[3] [after dining and copulating]. Accordingly, the precondition for sleep is a *lowering of the endogenous load in the ψ nucleus*, which makes the secondary function superfluous. In sleep an individual is in the ideal state of inertia, rid of his store of $Q\eta$ [p. 321].

In adults[4] this store is collected in the 'ego' [pp. 347–8]; we may assume that it is the *unloading of the ego* which determines and characterizes sleep. And here, as is immediately clear, we have the *precondition of psychical primary processes*.

It is not certain whether in adults the *ego* is completely relieved of its burden in sleep. In any case it[5] withdraws an enormous number of its cathexes, which, however, are restored on awakening, immediately and

1 [This is perhaps equivalent to the 'attention' mentioned in the next sentence and discussed at length in Part III (p. 384 ff. below).]

2 [This paragraph contains what was probably the first full statement of one of Freud's most momentous observations. The matter was touched on very briefly in the Fliess correspondence (above) and in Freud's contemporary lecture 'On Hysteria' (1895*g*), *RSE*, **2**, 291 ff.]

3 [Translator's italics.]

4 [In the MS.: '*beim Erwachsenen*' (cf. the next paragraph). In *Anf.*, 420, this was misread '*beim Erwachen*' ('on waking up').]

5 ['*Es*' in the MS.; '*er*' ('he') in *Anf.*, 420.]

without trouble. This contradicts none of our presuppositions; but it draws attention to the fact that we must assume that between neurons which are properly linked there are currents that affect the total level [of cathexis] as happens in intercommunicating pipes, although the height of the level in the different neurons need only be proportionate and not necessarily uniform [cf. p. 394 below].

The peculiarities of sleep reveal a number of things which it might not have been possible[1] to guess.

[337] Sleep is characterized by *motor paralysis* (*paralysis of the will*).[2] The will is the discharge of the total ψ $Q\eta$ [p. 342]. In sleep the spinal tonus is in part relaxed; it is probable that the motor ϕ discharge[3] is manifested in tonus; other innervations persist [in sleep] together with the sources of their excitation.

It is a highly interesting fact that the state of sleep begins and is evoked by a closure of those sense organs that are capable of being closed.[4] Perceptions should not be made during sleep, and nothing disturbs sleep more than the emergence of sense impressions, cathexes entering ψ from ϕ. This seems to indicate that during daytime a constant, even though displaceable, cathexis (*attention*) is sent into the pallium neurons, which receive perception from ϕ [p. 340], so that it may well be that the carrying out of the ψ primary processes is made possible with the help of this ψ contribution [p. 361].[5] Whether the pallium neurons themselves are already precathected, or adjoining nuclear neurons, remains to be seen. If ψ withdraws these pallium cathexes, the perceptions take place upon uncathected neurons and are slight, and perhaps not capable of giving an indication of quality from ω [p. 350].[6] As we have conjectured, along with the emptying of the ω neurons, the innervation of a discharge which increases attention comes to a stop as well. It is from *here*, too, that the enigma of hypnotizing would have to be

1 ['*liesse*' in the MS. *Anf.*, 421, has '*lässt*' ('may not be possible').]

2 [This is often insisted on in later writings, e.g. *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 496. The subject is expanded below, p. 363.]

3 [Here and at several points below a motor function is assigned to ϕ. This presumably refers to the kinaesthetic *sensory* motor function, the absence of which in sleep is explained by a withdrawal of ψ pallium precathexis (see pp. 359 *n.* 2 above and 411 *n.* 1 below, but also cf. pp. 350 *n.* 4 and 388 *n.* 7).]

4 [Cf. *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 21.]

5 [So in the MS. The sense, however, seems to imply ψ secondary processes.]

6 [The MS. reads: '. . . *vielleicht nicht im Stande von ω aus ein Qualz zu geben*'. *Anf.*, 421, reads incorrectly: '. . . *vielleicht nicht im Stande, von Wahrnehmungen aus ein Quantitätszeichen zu geben*' ('. . . perhaps not capable of giving an indication of quantity from perceptions'). – Something of the same sort as here is suggested in (among other places) the paper on the 'Mystic Writing-Pad' (1925*a*), *RSE*, **19**, 230 f.]

approached. The apparent unexcitability of the sense organs [in hypnosis] must rest on this withdrawal of the cathexis of attention.[1]

Thus, by an automatic mechanism, the counterpart of the mechanism of attention,[2] ψ excludes the ϕ impressions so long as it itself is uncathected.

But what is strangest of all is that during sleep ψ processes occur – dreams, which have many characteristics that are not understood.

[20] *The Analysis of Dreams*

Dreams exhibit every transition to the waking state and to a mixture with normal ψ processes; yet it is easy to sift out what is genuinely in the nature of a dream. [338]

(1) Dreams *are devoid of motor discharge* and, for the most part, of motor elements. We are paralysed in dreams [p. 362 above].

The easiest explanation of this characteristic is the absence of spinal precathexis owing to the cessation of ϕ discharge. The motor excitation cannot pass over the [?] barrier[3] when a neuron is uncathected [p. 344].[4] In other dream states movement is not excluded. This is not the most essential[5] characteristic of dreams.

(2) The connections in dreams are partly *nonsensical*, partly *feeble-minded*, or even meaningless or strangely crazy.

This latter characteristic is explained by the fact that in dreams the *compulsion to associate* prevails, as no doubt it does primarily in psychical life generally.[6] Two cathexes that are present simultaneously *must*, so it seems, be brought into connection. I have collected some comic examples of the dominance of this compulsion in waking life. (For

1 [Freud referred to this possibility again in his *Group Psychology* (1921*c*), *RSE*, **18**, 117 f., where a footnote gives references to other effects of the withdrawal of attention.]

2 [I.e. by withdrawal of the precathexis of attention.]

3 [*Anf*., 422, gives '*Schranke*', the usual word for 'barrier'. In the MS., however, the word appears to be '*Pyschranke*'; the 'Py' is particularly clearly written, in Roman script; the rest of the word, equally clear, is in Gothic. These two letters are quite unexplained and have simply been omitted in *Anf*.]

4 [See footnote 3, p. 362 above. The implication is that motor *tone* is reduced by the absence of kinaesthetic motor discharge. (See p. 415 below.) There is in addition the absence of motor discharge from ψ (see pp. 362 above and 364 below).]

5 ['*wesentlichste*' in the MS.; '*wesentliche*' ('essential') in *Anf*., 422.]

6 [The primary process is expressed in compulsory association. This is mentioned above (p. 343 f.). Freud had discussed this 'compulsion to associate' in the course of a long footnote to one of his case histories in *Studies on Hysteria* (1895*d*), *RSE*, **2**, 62 *n*. He applied it there already as an explanation of the senselessness of dreams; and he returned to the idea in *The Interpretation of Dreams* (1900*a*), ibid., **4**, 158–9.]

instance, some men from the provinces who were present at the time of the [bomb] outrage in the French Chamber concluded that as a sign of applause after every successful speech by a deputy – a shot was fired.)[1]

The two other characteristics, which are in fact identical, show that a part of the [dreamer's] psychical experiences [*Erfahrungen*] have been forgotten. Actually, indeed, all the biological experiences which ordinarily inhibit the primary process are forgotten, and this is owing to the lack of ego cathexis. The senselessness and illogicality of dreams are probably to be attributed to this very same characteristic. It seems as though ψ cathexes that have not been withdrawn level themselves off partly in the direction of their nearest facilitations and partly in the
[339] direction of their neighbouring cathexes. If the ego were completely unloaded, sleep would necessarily be dreamless.

(3) Dream ideas are of a hallucinatory kind; they awaken consciousness and meet with belief.[2]

This is the most important characteristic of sleep. It appears at once when there are alternating spells of sleeping [and waking]. One shuts one's eyes and hallucinates; one opens them and thinks in words. There are several explanations of the hallucinatory nature of dream cathexes. In the first place, it might be supposed that the *current* from ϕ to motility has [during waking life] prevented a retrogressive cathexis of the ϕ neurons from ψ,[3] and that when this current ceases ϕ is retrogressively cathected and the necessary precondition for [the generation of] quality thus fulfilled. The only argument against this is the consideration that the ϕ neurons, by the fact of being uncathected, should be protected against cathexis from ψ, just as is motility. It is distinctive of sleep that it reverses the whole situation here, that it suspends the motor discharge from ψ and makes the retrogressive one to ϕ possible. It is tempting to assign the determining role here to the great current of discharge in waking life, ϕ – motility.[4] Secondly, we might revert to the nature of the primary process and point out that the primary memory of a perception is always a hallucination and that only inhibition by the ego has taught us

1 [This anecdote was included in *The Interpretation of Dreams*, in a rather different connection, *RSE*, **5**, 447. Modern behavioural scientists speak in this connection of 'autoshaping' and 'adjunctive behaviours'.]

2 [This fact is reasserted and its importance insisted on in Freud's metapsychological paper on dreams (1916–17*f* [1915]), ibid., **14**, 203–4.]

3 [*Anf.*, 423, has made some slight changes in the order of these last few words; but the sense has not been affected. – Here we have an approach to what Freud was later to call 'regression'. His use of the concept can be found discussed in Appendix A at the end of Part I (p. 369 below).]

4 [This explanation of regression is considered and criticized in *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 486.]

never to cathect a perceptual image in such a way that it is able to transfer [$Q\eta$] retrogressively to ϕ. [See pp. 350 and 351 above.] To make the hypothesis more acceptable, it might be added in this connection that in any case the conduction ϕ–ψ takes place more easily than the conduction ψ–ϕ; so that a ψ cathexis of a neuron, even if it greatly exceeds the perceptual cathexis of the same neuron, need nevertheless still not[1] conduct retrogressively. This explanation is further supported by the circumstance that in dreams the vividness of the hallucination is directly proportionate to the importance – that is, to the quantitative cathexis – of the idea concerned. This indicates that it is Q which determines the hallucination. If a perception comes from ϕ in waking life, it is no doubt [340]
made clearer by ψ cathexis (interest), but not more vivid; it does not alter its quantitative characteristic.[2]

(4) The aim and sense of dreams (of normal ones, at all events) can be established with certainty. They [dreams] are *wish fulfilments*[3] – that is, primary processes following upon experiences of satisfaction [p. 344 above]; and they are only not recognized as such because the release of pleasure (the reproduction of traces of pleasurable discharges [pp. 336–7][4]) in them is slight, because in general they run their course almost without affect (without motor release). That this is their nature is, however, very easily shown. It is precisely from this that I am inclined to infer *that primary wishful cathexis*, *too*, *was of a hallucinatory nature* [p. 344].

(5) It is noteworthy how poorly dreams are remembered and how little harm they do as compared with other primary processes. But this is easily explained from the fact that, for the most part, they follow old facilitations and thus make no change [in them], that ϕ experiences[5] are held back from them and that, owing to the paralysis of motility, they [dreams] do not leave traces of discharge behind them.

(6) It is interesting, furthermore, that *consciousness* in dreams furnishes quality with as little trouble as in waking life. This shows that consciousness does not cling to the ego but can become an addition to

1 [In the MS.: '*doch noch nicht*'. *Anf*., 423, omits '*noch*' ('still').]

2 [The question of clarity and vividness in dreams receives much more complicated treatment in *The Interpretation of Dreams* (1900*a*): e.g. *RSE*, **4**, 293–5.]

3 [The first hint of this discovery was in a letter to Fliess of March 4, 1895 (Letter 22, p. 240 above). The dream hinted at there is reported more fully in *The Interpretation of Dreams* (*RSE*, **4**, 111 f.) as a 'dream of convenience'. The final confirmation was reached in the analysis of the dream of 'Irma's injection' dreamt by Freud on the night of July 23–24, 1895, only a couple of months earlier than the present discussion. It is reported briefly in the next section.]

4 [In the MS.: '*Lustabfuhrspuren*'. In *Anf*., 424, '*Lustabfuhren*' ('pleasurable discharges').]

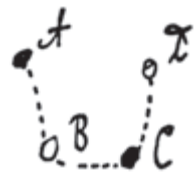
5 ['ϕ *Erlebnisse*' in the MS.; *Anf*., 424, misprints this 'ψ *Erlebnisse*'.]

any ψ processes. It warns us, too,[1] against possibly identifying primary processes with unconscious ones. *Here are two invaluable hints for the future!*[2]

[341] If, when the memory of a dream is retained, we enquire into its content, we find that the meaning of dreams as wish fulfilments is concealed by a number of ψ processes: all of which are met with once more in neuroses and characterize the latter's pathological nature [p. 361 above].[3]

[21] *Dream Consciousness*

Consciousness of dream ideas is above all discontinuous. What becomes conscious is not a whole succession of associations, but only separate stopping points in it. Between these there lie unconscious intermediate links which we can easily discover when we are awake. If we investigate the reasons for this skipping, here is what we find. Let *A* [Fig. 15] be a dream idea which has become conscious and which leads to *B*. But instead of *B*, *C* is found in consciousness, and this is because [it][4] lies on the pathway between *B* and a *D* cathexis which is simultaneously present. Thus there is a diversion brought about by a simultaneous cathexis, of a different kind, which, incidentally, is not itself conscious. For that



[Fig. 15]

reason, then, *C* has taken the place of *B*, though *B* fits in better with the connection of thought, with the wish fulfilment.[5]

For instance, [in a dream of my own] R. has given an injection of *propyl*

1 ['*Auch*' in the MS. Omitted in *Anf.*, 424.]

2 [In the MS. this sentence forms the conclusion of the paragraph and obviously refers back to the two points just made in it. In *Anf.*, 424, the sentence is made into the first one of the following paragraph, as though referring forwards. – Incidentally, the 'two invaluable hints' might be quotations from one of Freud's latest writings some thirty years later. But he had in fact already said something to the same effect in his Preface, written in 1888, to his translation of Bernheim's book on suggestion. See p. 90 above.]

3 [Cf. a similar passage in *The Interpretation of Dreams* (1900*a*), where these pathological processes are enumerated and described: *RSE*, **5**, 532 ff.]

4 [An '*es*' ('it') which the sense seems to require here is absent in the MS. It is inserted in *Anf.*, 425.]

5 [From this point 'ideas' replace neurons completely. See pp. 344 *n.* 3 and 353 *n.* 2 above.]

to A. I then see *trimethylamine* before me very vividly, hallucinated as a formula. Explanation:[1] The thought simultaneously present [*D*] is the [342]
sexual nature of A.'s illness. Between this thought and the propyl [*A*] there is an association from sexual chemistry [*B*], which I had discussed with W. Fl[iess], in the course of which he had drawn my special attention to trimethylamine. This now became conscious [*C*] owing to pressure from both sides.

It is very puzzling that neither the intermediate link [*B*] (sexual chemistry) nor the diversionary idea [*D*] (the sexual nature of the illness) becomes conscious as well, and an explanation of this is called for. One would suppose that the cathexis of *B* or *D* alone is not intense enough to make its way through to a retrogressive hallucination, but that *C*, cathected from both sides, would bring this about. In the example chosen, however, *D* (the sexual nature [of the illness]) was certainly as intense as *A* (the propyl injection) and the derivative of these two, the chemical formula [*C*], was immensely vivid. The puzzle about unconscious intermediate links applies equally to waking thought, where similar events are of daily occurrence. But what remains characteristic of dreams is the *ease with which Qη is displaced*[2] [*Verschiebung*]^{T} *and* accordingly the *replacement of B by a C which is superior to it quantitatively*.

Similarly with the fulfilment of wishes in dreams generally. What happens is not, for instance, that the wish becomes conscious and that its fulfilment is then hallucinated, but only the latter: the intermediate link is left to be inferred. It has quite certainly been passed through, but without being able to develop qualitatively. It is evident, however, that the cathexis of the wishful idea cannot possibly be stronger than the motive impelling to it. Thus the psychical passage [of excitation] in dreams takes place in accordance with *Q*; but it is not *Q* which decides the question of becoming conscious.

1 [What we have here is, of course, a very short account of the famous dream of 'Irma's injection' (referred to in footnote 3, p. 365 above), which is used as the 'specimen dream' in *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 94–108 and 260 ff. The present MS. names the patient 'A.', and the doctor 'R.'. The editors of *Anf*. have substituted the pseudonyms chosen by Freud in his full account: 'Irma' for the patient and 'O' ('Otto') for the doctor. – For the last part of this sentence the MS. reads: '*dann sehe ich vor mir* TRIMETHYLAMIN *sehr lebhaft*, *halluc als Formel*. *Erklärg: . . .*' *Anf*., 425, has: '*dann sehe ich vor mir* TRIMETHYLAMIN *sehr lebhaft*, *halluziniere als formale Erklärung: . . .*' ('I then see before me *trimethylamine* very vividly, hallucinated as a formal explanation: . . .') The word '*Formel*' followed by a full stop is quite clear in the MS. and is moreover confirmed in the next paragraph and is also confirmed in *The Interpretation of Dreams*, *RSE*, **4**, 96.]

2 [This word appears frequently above, with the same sense, but only at this point does its later technical meaning become apparent – presumably because neurons are now replaced with 'ideas'.]

It should also perhaps be inferred from dream processes that consciousness arises *during* the passage of a $Q\eta$ – that is, that it is not awakened by a *constant*[1] cathexis. It should further be suspected that an intense current of $Q\eta$ is not favourable to the generation of consciousness, since it is to the outcome of the movement that it [consciousness] [343] attaches – to a comparatively quiet lingering, as it were, of the cathexis. It is hard to penetrate to what it is that really determines consciousness in view of these mutually contradictory preconditions. We must in addition take into account the circumstances in which *consciousness*[2] arises in the secondary process.

The peculiarity of dream consciousness mentioned above may perhaps be explained by the fact that the backward flow of a current of $Q\eta$ to ϕ is incompatible with a more energetic current to the ψ paths of association. Other conditions seem to apply to the ϕ processes of consciousness.

25 Sept 95.[3]

1 [Translator's italics. – The same inference would have to follow from the fact that its decisive 'mechanical' characteristic is of a temporal nature (see p. 334 ff. above).]

2 [This word is underlined in the MS. The sense would seem to call for the underlining of 'secondary process' instead.]

3 [This date at the end of Part I of the MS. of the 'Project' is wrongly transferred in *Anf.*, 427, to the beginning of Part II. – The day of the month may possibly be read as '28'.]

APPENDIX A

FREUD'S USE OF THE CONCEPT OF REGRESSION

The concept of regression, foreshadowed in the last two sections of Part I of the 'Project', was to play an increasingly important part in Freud's theories. [344]

In a footnote added in 1914 to Chapter VII (B) of *The Interpretation of Dreams* (*RSE*, **5**, 485 *n.*), Freud himself traced back the idea of regression to the thirteenth-century scholastic philosopher Albertus Magnus and to Hobbes's *Leviathan* (1651). But he seems to have derived it more directly from Breuer's theoretical contribution to *Studies on Hysteria* (1895*d*), *RSE*, **2**, 169, published only a few months before he himself wrote the present work. Breuer there described the retrogressive movement of an excitation from an idea or mnemic image back to a perception (or hallucination) in almost exactly the same way as Freud does here. Both writers used the same word '*rückläufig*', which is here translated 'retrogressive'.

The actual German word '*Regression*' appeared first, so far as we know (in a similar connection), some eighteen months later than this in a draft sent to Fliess on May 2, 1897 (Draft L, p. 277 above). But its first *publication* was in *The Interpretation of Dreams* (1900*a*), in the passage to which the footnote quoted at the beginning of this Appendix was subsequently attached.

As time went on, the term came to be used in a variety of ways, which were at one point[1] classified by Freud as 'topographical', 'temporal' and 'formal'.

'Topographical' regression is the kind introduced by Breuer and employed in the 'Project', and it forms the main topic of Chapter VII (B) of *The Interpretation of Dreams* (1900*a*). It owes its name to the diagrammatic picture of the mind in that chapter (*RSE*, **5**, 480), which represents psychical processes as advancing from the perceptual to the motor end of the psychical apparatus. In topographical regression, the excitation is conceived of as moving backwards towards the perceptual end. The term is thus essentially a description of a psychological phenomenon.

'Temporal' regression has closer relations with clinical material. It emerges first, but without any explicit reference to 'regression', in the 'Dora' case history, which was written in 1901, though only published four years later (1905*e*). It occurs there in [345] connection with a discussion of perversions (ibid., **7**, 45–7). What is suggested is that, if some accidental event in later life inhibits the normal development of sexuality, the consequence may be the reappearance of the 'undifferentiated' sexuality of childhood.[2] Freud went on to produce for the first time a favourite analogy: 'A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into

1 In a paragraph added to *The Interpretation of Dreams*, also in 1914: *RSE*, **5**, 490.

2 This is, of course, an early hint at what was soon to be described as the 'polymorphously perverse' disposition of children. (Cf. *Three Essays*, 1905*d*; ibid., **7**, 169 f.)

old channels which had formerly seemed fated to run dry.' The same hypothesis, illustrated by the same analogy, appeared more than once in the *Three Essays* (e.g. *RSE*, **7**, 151), but again without, in the first edition of the work, mentioning the term 'regression', though it occurs in several passages added in later editions (e.g. ibid., 212, added in 1915).[1] This kind of regression was already recognized in the *Three Essays* as playing a part not only in perversions but also in neuroses (ibid., 153), and even in the normal choice of an object at puberty (ibid., 201 f.).

It was not clearly realized at first that there are in fact two different kinds of mechanism involved in this 'temporal' regression. It might be a question simply of a return to an earlier libidinal object or it might be a question of a return of the libido itself to earlier ways of functioning. Both these kinds are, in fact, already implicit in the discussion of the perversions in the *Three Essays*, where it is plain that there may be a return both to an earlier sexual *object* and to an earlier sexual *aim*. (This distinction is brought out most clearly in Lecture XXII of the *Introductory Lectures* (1916–17*a*), ibid., **16**, 300 f.) Just as the first of these types of temporal regression is particularly characteristic of hysteria, so the second type is specially associated with obsessional neurosis. Examples of this connection were already given in the 'Rat Man' case history (1909*d*), e.g. ibid., **10**, 185–6. But a full realization of its importance was arrived at only with the establishment of the hypothesis of fixation points[2] and pregenital organizations in the development of the libido. It was then possible to grasp the effect of frustration in causing a regression of the libido to some early fixation point. This was made especially clear in two papers – 'Types of Onset of Neurosis' (1912*c*), ibid., **12**, 228, and 'The Disposition to Obsessional Neurosis' (1913*i*),
[346] ibid., **12**, 318–19. But it had already been suspected that a similar process must be in operation, too, in more severe disorders – in schizophrenia and paranoia – evidence for which hypothesis was to be seen in the study of Schreber's autobiography (1911*c*), ibid., **12**, 53 f.

If we accept Freud's late definition of 'defence' (in *Inhibitions, Symptoms and Anxiety*, 1926*d*; ibid., **20**, 144) as a 'general designation for all the techniques which the ego makes use of in conflicts which may lead to a neurosis', we may perhaps regard all these examples of 'temporal' regression as mechanisms of defence. This, however, can scarcely be said, except in a very roundabout sense, of another clinical manifestation of regression – the transference – which was discussed by Freud in his technical paper on 'The Dynamics of Transference' (1912*b*), ibid., **12**, 95–6. This particular form of temporal regression was the subject of some further interesting remarks in the 'History of the Psychoanalytic Movement' (1914*d*), ibid., **14**, 7–8.

Freud's third kind of regression – 'formal' regression – described by him as occurring 'where primitive methods of expression and representation take the place of the usual ones' (*The Interpretation of Dreams*, 1900*a*; ibid., **5**, 490) – has been discussed by him mainly in Lectures X, XI and XIII of the *Introductory Lectures* (1916–17*a*), in connection with dreams, symbolism and linguistics.

Freud's own classifications of these various kinds of regression were not uniform. In the earliest of them, in the *Five Lectures* (1910*a*), ibid., **11**, 47, he described 'temporal' and 'formal' regression. In the paragraph included in 1914 in *The Interpretation*

1 Freud evidently felt some reluctance at first to extending the application of the term from its 'topographical' to its 'temporal' use.

2 Cf. the footnote on the term 'fixation', p. 152 above.

of Dreams, *RSE*, **5**, 490, he added 'topographical' regression. In his metapsychological paper on dreams (1916–17*f*), written in 1915, he spoke (ibid., **14**, 197–8) of two sorts of 'temporal' regression, 'one affecting the development of the ego and the other that of the libido'; and a few pages later (ibid., 202) he referred to a 'topographical' regression and distinguished it from 'the previously mentioned *temporal* or developmental regression'. Lastly, in Lecture XIII of the *Introductory Lectures* (1916–17*a*), ibid., **15**, 184, he differentiated a 'formal' from a 'material' regression.

In considering these slight variations of terminology, it is as well to recall Freud's final comment in the 1914 paragraph in *The Interpretation of Dreams* (ibid., **5**, 490) which we have quoted more than once: 'All these three kinds of regression are, however, one at bottom and occur together as a rule; for what is older in time is more primitive in form and in psychical topography lies nearer to the perceptual end.'

PART II
PSYCHOPATHOLOGY

[347] The first part of this project contained what could be deduced from the basic hypotheses,[1] more or less *a priori*,[2] moulded and corrected in accordance with various factual experiences. This second part seeks to infer from the analysis of pathological processes some further determinants of the system founded on the basic hypotheses; a third part will hope to construct from the two preceding ones the characteristics of the normal passage of psychical events.

A.[3] PSYCHOPATHOLOGY OF HYSTERIA

[1] *Hysterical Compulsion*

I start off from things which occur in hysteria without necessarily being peculiar to it. – Every observer of hysteria is struck in the first place by the fact that hysterical patients are subject to a *compulsion* [*Zwang*] which is exercised by *excessively intense* ideas.[4] An idea will, for instance, emerge in consciousness with particular frequency without the passage [of events] justifying it; or the arousing of this idea[5] will be accompanied by psychical consequences that are unintelligible. The emergence of the excessively intense idea brings with it consequences which, on the one hand, cannot be suppressed and, on the other hand, cannot be understood – release of affect, motor innervations, impediments. The subject is by no means unaware of the striking character of the situation.

[348] Excessively intense ideas also occur normally. They lend the ego its individuality. We are not surprised at them if we know their genetic development (upbringing, experiences) and their motives. We are accustomed to regarding such *excessively intense* ideas as the product of strong and justifiable motives. Hysterical *excessively intense ideas* strike

1 [Here, and four lines below, this word is in the plural in the MS., though *Anf.*, 427, gives it in the singular.]

2 [Translator's italics.]

3 [The MS. contains no 'B' corresponding to this 'A'.]

4 ['*Überstark*' (cf. p. 319 above). The same word is used by Freud in the same connection in the 'Dora' analysis (1905*e* [1901]), *RSE*, **7**, 49, where it is equated with Wernicke's term '*überwertig*' ('supervalent'), used in its turn by Breuer in *Studies on Hysteria* (1895*d*), ibid., **2**, 220. The underlying notion of the present passage had already been stated by Freud in his discussion of the case of Emmy von N. in the latter volume (ibid., **2**, 76 f.). Cf. the lecture 'On Hysteria' (1895*g*), ibid., **2**, 291 ff.; also Wernicke (1900, 140).]

5 [The MS. has either '*dieser N*' [*Neurone*] ('of these neurons') or '*dieser V*' [*Vorstellung*] ('of this idea'). *Anf.*, 427, chooses the former, but the latter seems to make simpler sense.]

us, on the contrary, by their oddity; they are *ideas* which in other people have no consequences and of whose importance we can make nothing. They appear to us as intruders and usurpers, and accordingly as ridiculous.

Thus, *hysterical compulsion* is (1) *unintelligible*, (2) *incapable of being resolved by the activity of thought*, (3) *incongruous* in its structure.

There is a *simple neurotic* compulsion which may be contrasted with the hysterical kind. For instance, a man may have run into danger by falling out of a carriage, and driving in a carriage may after that be impossible for him. This compulsion is (1) intelligible, since we know its origin and (3)[1] congruous, since the association with danger justifies the link between driving in a carriage and fear. It too, however, is not capable of being resolved by the activity of thought. The latter characteristic is not to be termed entirely pathological: our normal excessively intense ideas, too, are often incapable of being resolved. One would regard neurotic compulsion as not pathological at all if experience did not show that in healthy people a compulsion such as this persists for only a short time after its occasion, and gradually disintegrates. Thus the persistence of the compulsion is pathological and points to a *simple neurosis*.[2]

Now our analyses show that a hysterical compulsion is *resolved* immediately it is *explained* (made intelligible). Thus these two characteristics are in essence one. In analysis we learn, too, the process by which the appearance of absurdity and *incongruity* comes about. The outcome of analysis is, expressed in general terms, as follows:

Before the analysis, *A* is an excessively intense idea, which forces its way into consciousness too often, and each time gives rise to weeping. The subject does not know why he weeps at *A*; he regards it as absurd but cannot prevent it.

After the analysis, it has been discovered that there is an idea *B*, which justifiably gives rise to weeping and which justifiably recurs frequently so long as a certain complicated psychical action has not been performed against it by the subject. The effect of *B* is not absurd; it is intelligible to the subject and can even be combated by him. [349]

B stands in a particular relation to *A*.

1 [So in the MS. *Anf.*, 428, has altered this to '(2)'. The '3' refers back, of course, to the list just above.]

2 [This is not a term commonly used by Freud in any of his contemporary discussions of the classification of the neuroses. It does appear in his second paper on the neuropsychoses of defence (1896*b*), *RSE*, **3**, 177, where it is used of what he later called the 'actual neuroses' – neurasthenia and anxiety neurosis – as contrasted with the 'psychoneuroses', hysteria and obsessional neurosis. It seems, however, as though he must be using the term differently in the present connection.]

For there has been an occurrence which consisted of *B*+*A*. *A* was an incidental circumstance; *B* was appropriate for producing the lasting effect. The reproduction of this event in memory has now taken a form of such a kind that it is as though *A* had stepped into *B*'s place. *A* has become a substitute, a *symbol* for *B*. Hence the incongruity: *A* is accompanied by consequences which it does not seem worthy of, which do not fit in with it.

The *formation of symbols* also takes place normally. A soldier will sacrifice himself for a many-coloured scrap of stuff on a pole, because it has become the symbol of his fatherland, and no-one thinks that neurotic.[1]

But a hysterical *symbol* behaves differently. The knight who fights for his lady's glove *knows*, in the first place, that the glove owes its importance to the lady; and, secondly, he is in no way prevented by his adoration of the glove from thinking of the lady and serving her in other respects. The *hysteric*, who weeps at *A*, is quite unaware that he is doing so on account of the association *A*–*B*, and *B* itself plays no part at all in his psychical life. The symbol has in this case taken the place of the *thing* entirely.

This assertion is correct in the strictest sense. We [can] convince [ourselves] that whenever anything is evoked, from outside or by association, which should in fact cathect *B*, *A* enters consciousness instead of it. Indeed, one can infer the nature of *B* from the provoking causes which – in a remarkable fashion – evoke *A*.

[350] We can sum the matter up: *A* is compulsive, *B* is repressed (at least from consciousness).

Analysis has led to the surprising conclusion: that for every compulsion there is a corresponding *repression*, that for every excessive intrusion into consciousness there is a corresponding amnesia.

The term 'excessively intense' points to quantitative characteristics. It is plausible to suppose that *repression* has the quantitative meaning of being denuded of *Q*, and that the sum of the two [of the compulsion and the repression] is equal to the normal. If so, only the distribution has changed. Something has been added to *A* which has been subtracted

1 [The same example reappears in *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 156–7. – In this discussion Freud seems for the most part to be using 'symbolization' in the very general sense of 'displacement'. In his contributions to *Studies on Hysteria* (1895*d*) he had used the term in the more restricted sense of the 'conversion' of mental states into physical sensations. (See, for instance, ibid., **2**, 159–61. See also Breuer's section, 'Hysterical Conversion', ibid., **2**, 186 ff.) These uses are only loosely connected with those found more often in Freud's later writings, especially in connection with dreams. In these an essential condition seems to be that the meaning of the symbol should be absent from consciousness, as is not the case in the next paragraph. The various uses of the concept of 'symbol' were considered by Freud in Lecture X of the *Introductory Lectures* (1916–17*a*), ibid., **15** (especially 132 f.).]

from *B*. The pathological process is one of *displacement*, such as we have come to know in dreams – a primary process therefore.[1]

[2] *The Genesis of Hysterical Compulsion*

Several significant questions now arise. Under what conditions does a pathological symbol formation of this kind [and] (on the other hand) repression come about? What is the operative force in this? In what state are the neurons of the excessively intense idea and those of the repressed one?

Nothing could be surmised here and nothing further constructed, if it were not that clinical experience teaches us two facts. Firstly, repression is brought to bear invariably on ideas which evoke a distressing affect (unpleasure) in the *ego*, secondly on idea[s] from sexual life.[2]

It may already be suspected that it is this unpleasurable affect which puts repression into operation. We have already, indeed, assumed the existence of a *primary defence* which consists in the current of thought being reversed as soon as it comes up against a neuron the cathecting of which releases unpleasure. [Cf. pp. 346–7 and 355 above.] The justification for this [hypothesis] arose from two experiences: (1) that the cathexis of this neuron was certainly not the one that was being sought for, when the thought process aimed originally at establishing a situation of ψ satisfaction; (2) that when an experience of pain was brought to an end by a reflex, the hostile perception was replaced by another [p. 347].

We can, however, convince ourselves more directly of the part played [351]
by the defensive affect. If we investigate the state of the repressed [idea] *B*, we discover that that idea is easy to find and bring into consciousness. This is a surprise, for it might well have been supposed that *B* was really forgotten, that no memory trace of *B* remained in ψ. But no, *B* is a mnemic image like any other; it is not extinguished. But if, as is usual, *B* is a complex of cathexes, then a *resistance* arises, which is uncommonly large and hard to defeat,[3] against activity of thought with *B*. We can at once recognize in this resistance against *B* the amount of the *compulsion* exercised by *A*, and we may conclude that the force which in the past

1 [Much of the foregoing argument reappears, on rather different lines, in the 'Dora' analysis (1905*e*), *RSE*, 7, 49–50.]

2 [So in the MS. It will be seen presently (pp. 376–7 below) that the intended meaning is that an idea must be *both* distressing *and* sexual in order to be repressed.]

3 ['*schwer zu besiegender*' in the MS. *Anf.*, 430, has '*schwer zu beseitigender*' ('hard to get rid of').]

repressed *B* is to be seen here at work once more.[1] At the same time we learn something else. We only knew, indeed, that *B* cannot become *conscious*; nothing was known about the relation of *B* to thought cathexis. We now learn that the resistance is directed against thought being in any way concerned with *B*, even if it [*B*] has already been made partly conscious. So that instead of excluded from consciousness we may put *excluded from the process of thought*.

Thus there is a defensive process emanating from the *cathected ego* which results in hysterical repression and, along with it, in hysterical compulsion. To that extent the process seems to be differentiated from the ψ primary processes.

[3] *Pathological Defence*

Nevertheless, we are far from a solution. As we know, the outcome of *hysterical repression* differs very widely from that of normal defence, of which we have precise knowledge. It is quite generally the case that we avoid thinking of what arouses only unpleasure, and we do this by directing our thoughts to something else. If, however, we accordingly[2] manage to bring it about that the incompatible [idea] *B* seldom emerges in our consciousness, because we have so far as possible kept it isolated,
[352] yet we never succeed in forgetting *B* in such a way that we could not be reminded of it by fresh perception. Now an arousal of this kind cannot be precluded in hysteria either; the difference consists only in the fact that then, instead of *B*, *A* always becomes conscious – that is, is cathected. Thus it is *symbol formation* of this stable kind which is the function that goes beyond normal defence.

The most obvious explanation of this increased function would be that the greater intensity of the defensive affect is responsible for it. Experience shows, however, that the most distressing memories, which must necessarily arouse the greatest unpleasure (the memory of remorse over bad actions), cannot be repressed and replaced by symbols. The existence of a second precondition for pathological defence [p. 375 above] – sexuality – also points to the fact that the explanation must be looked for elsewhere. It is quite impossible to suppose that distressing

1 [This observation of the identity of the forces at work in resistance and repression was to become, as Freud remarked more than once in later years, the cornerstone of psychoanalysis. See, for instance, the *Autobiographical Study* (1925*d*), *RSE*, **20**, 25–6. The observation is already to be found in *Studies on Hysteria* (1895*d*). See, e.g., ibid., **2**, 139 f. Cf. also Freud (1895*g*), ibid., **2**, 300 and *n*. 2.]

2 [*Anf*., 431, prints '*dann noch*' ('in addition to this'). The MS. is doubtful, but the *GW* transcription reads '*dadurch*', which seems to make better sense.]

sexual affects so greatly exceed all other unpleasurable affects in intensity. It must be another characteristic of sexual ideas that can explain how it is that sexual ideas are alone subjected to repression.

One further remark must be added here. Hysterical repression evidently takes place with the help of *symbol formation*, of *displacement* on to other neurons. We might think, then, that the riddle resides only in the mechanism of this displacement, that there is nothing to be explained about repression itself. We shall hear, however, in connection with the analysis of, for instance, obsessional neurosis, that there *repression without* symbol formation occurs, and indeed that there repression and substitution are chronologically separated. Accordingly, the process of repression remains as the core of the riddle.

[4] *The Hysterical Proton Pseudos*[1]

We have seen that hysterical compulsion originates from a peculiar kind [353]
of *Qη* motion (symbol formation), which is probably a *primary process*, since it can easily be demonstrated in dreams; [and we have seen] that the operative force of this process is *defence* on the part of the ego, which here, however, is performing more than its normal function [p. 376 above].[2] We need an explanation of the fact that in the case of an *ego process* consequences follow to which we are accustomed only with primary processes. We must expect to find special psychical determinants here. We know from clinical evidence that all this only occurs in the *sexual* sphere; so perhaps we shall have to explain the special psychical determinant from natural characteristics of sexuality.

Now, as it happens, there is a special psychical constellation in the sexual sphere which might be of service for our purpose. I will illustrate it (it is known to us empirically) by an example.[3]

1 [These words are in Latin script here in the MS., but in Greek script at the beginning of the next section. *Anf*., 432 and 435, prints both headings in Greek script. The term occurs in Aristotle's *Prior Analytics* (Book II, Chapter 18, 66a, 16), a work dealing with the theory of the syllogism which was later included in what came to be called the *Organon*. The chapter deals with false premises and false conclusions, and the particular sentence asserts that a false statement is the result of a preceding falsity ('*proton pseudos*'). Andersson (1962, 195–6) has, however, shown that a Viennese physician, Max Herz, used the same term in a similar context in a paper read by him before the neurological section of a scientific congress in Vienna in 1894. Of this section Freud was then the secretary. (Cf. a letter to Fliess of February 7, 1894, *Anf*., 91, Letter 16.)]

2 [In the MS.: '*welche aber hier mehr leistet als normal*'. *Anf*., 432, inserts a '*nicht*' before the '*mehr*' ('is performing no more'). There is no sign whatever in the MS. of '*nicht*', which is in any case contra-indicated by the sense.]

3 [Emma figures prominently in the Fliess correspondence. See Editors' footnote 2, p. 240 above. Cf. Schur (1966*a*).]

Emma is subject at the present time to a compulsion of not being able to go into shops *alone*. As a reason for this, [she produced] a memory from the time when she was twelve years old (shortly after puberty). She went into a shop to buy something, saw the two shop assistants (one of whom she can remember) laughing together, and ran away in some kind of *affect of fright*. In connection with this, she was led to recall that the two of them were laughing at her clothes and that one of them had pleased her sexually.

The relation of these fragments [to one another] and the effect of the experience are alike unintelligible. If she felt unpleasure at her clothes being laughed at, that must have been corrected long ago, ever since she has been dressing as a [grown-up] lady. Moreover, it makes no difference to her clothes whether she goes into a shop alone or in company. That she is not simply in need of protection is shown by the fact that, as happens with agoraphobia, even the company of a small child is enough to make her feel safe. And there is the quite incongruous fact that one of them pleased her; it would make no difference to this either if she were accompanied. Thus the memories aroused explain neither the compulsion nor the determination of the symptom.

Further investigation now revealed a second memory, which she denies
[354] having had in mind at the moment of Scene I. Nor is there anything to prove this. On two occasions when she was a child of eight she had gone into a small shop to buy some sweets, and the shopkeeper had grabbed at her genitals through her clothes. In spite of the first experience she had gone there a second time; after the second time she stopped away. She now reproached herself for having gone there the second time, as though she had wanted in that way to provoke the assault. In fact a state of 'oppressive bad conscience' is to be traced back to this experience.

We now understand Scene I (shop assistants) if we take Scene II (shopkeeper) along with it. We only need an associative link between the two. She herself pointed out that it was provided by the *laughing*: the laughing of the shop assistants had reminded her of the grin with which the shopkeeper had accompanied his assault. The course of events can now be reconstructed as follows. In the shop the two assistants were *laughing*; this laughing aroused (unconsciously) the memory of the shopkeeper. Indeed, the situation had yet another similarity [to the earlier one]: she was once again in a shop alone. Together with the shopkeeper she remembered his grabbing through her clothes; but since then she had reached puberty. The memory aroused what it[1] was certainly not able to

1 ['*sie*' in the MS., which grammatically can only refer to the memory.]

at the time, a *sexual release*, which was transformed into anxiety. With this anxiety, she was afraid that the shop assistants might repeat the assault, and she ran away.

It is quite certainly established that two kinds of ψ processes are mixed up together here, that the memory of Scene II (shopkeeper) occurred in quite a different state from the other one. What happened can be represented thus [Fig. 16]:

[Fig. 16]

Of these, the blacked-in ideas[1] are perceptions which are also [consciously] remembered. The fact that the sexual release too[2] entered consciousness is proved by the otherwise incomprehensible idea that the laughing shop assistant had pleased her. The outcome – not to remain in the shop alone on account of the danger of assault – is quite rationally constructed having regard to all the pieces of the associative process. However, nothing of the process (represented underneath[3]) entered consciousness except the element clothes; and thought operating *consciously* has made two false connections in the material at its disposal (shop assistants, laughing, clothes, sexual feeling): that she was being laughed at on account of her clothes and that one of the shop assistants excited sexual pleasure in her.[4] [355]

1 [I.e. those represented by blacked-in circles.]

2 ['*auch*' in the MS. Omitted in *Anf.*, 434.]

3 ['*unten dargestellten*' in the MS. This refers to the unblacked-in circles in the lower part of the diagram. (The blacked-in circles in the upper row stand, as in the case of Fig. 15, p. 366 above, for *conscious* elements; the lower row, of unblacked-in circles, stand for *unconscious* elements.) The editors of *Anf.* seem to have misunderstood this and to have supposed that the phrase related to the position of the diagram on the page. They accordingly altered it to '*oben dargestellten*' ('represented above'), apparently under the impression that this was a slip of Freud's, for the diagram is 'above' in the MS., just as it is in *Anf.*, 434.]

4 ['False connections' had been discussed at length by Freud in his case history of Emmy von N. See *Studies on Hysteria* (1895*d*), *RSE*, **2**, 60–3 *n*. Elsewhere in his early writings the term is more often used specifically of displacement of affect, e.g. in the first paper on the neuropsychoses of defence (1894*a*), ibid., **3**, 49.]

The whole complex (unblacked-in[1] [circles]) is represented in consciousness by the one idea clothes, clearly the most innocent one. Here a repression accompanied by symbol formation has taken place. The fact that the outcome – the symptom – is then quite rationally constructed [see above], so that the symbol plays no part in it, is in point of fact a peculiarity of the case.

It might be said that it is quite usual, as happens here, for an association to pass through unconscious intermediate links until it comes to a
[356] conscious one.[2] In that case, the element which enters consciousness is probably the one that arouses special interest. In our example, however, it is noticeable precisely that the element which enters consciousness is not the one that arouses interest (assault) but another one, as a symbol (clothes). If we ask ourselves what may be the cause of this interpolated pathological process, only one presents itself – the *sexual release*, of which there is also evidence in consciousness. This is linked to the memory of the assault; but it is highly noteworthy that it [the sexual release] was not linked to the assault when this was experienced [*erlebt*]. Here we have the case of a memory arousing an affect which it did not arouse as an experience, because in the meantime the change [brought about] in puberty had made possible a different understanding of what was remembered.[3]

Now this case is typical of repression in hysteria. We invariably find that a memory is repressed which has only become a trauma by *deferred action* [*nachträglich*][T]. The cause of this state of things is the retardation of puberty as compared with the rest of the individual's development.

1 [In the MS.: '*lichtgehalten*'. *Anf.*, 434, alters this to '*gebrochene Linien*' ('broken lines'). – Incidentally, this is a striking example of the use of the word 'complex' in the sense of a repressed group of ideas, whose introduction is usually attributed to the Zürich school. See an Editors' Note to a paper of Freud's on legal proceedings (1906*c*), *RSE*, **9**, 80 *n.* 2. – Cf. also footnote 2, p. 177 above.]

2 [This sentence does not read quite grammatically in the MS. and has been rearranged in *Anf.*, 435, and *GW*, **Nachtr.**, 447, as given above. There is no question about its meaning.]

3 [The hypothesis stated in this sentence (which is discussed in the two following sections) governed Freud's views on the aetiology of hysteria throughout this early period. The hypothesis was first hinted at in a letter to Fliess dated June 12, 1895, and formally advanced in a letter dated October 15, 1895, where he described it as 'the great clinical secret'. He examined it shortly after writing the present work in a long footnote to his second paper on the neuropsychoses of defence (1896*b*), *RSE*, **3**, 177 *n.* 1, where further references can be found. The whole idea had the ground cut from under it by the discovery a year or two later of infantile sexuality and the recognition of the persistence of unconscious drive impulses. Nevertheless, the notion of the 'deferred action' of a trauma did not lose its whole validity, as is shown by a footnote to the 'Wolf Man' case history (1918*b*), ibid., **17**, 40 *n.* 1.]

[5] *Determinants of the* πρῶτον ψεῦδος ὑστ*[*ερικόυ*]*[1]

Although it does not usually happen in psychical life that a memory arouses an affect which it did not give rise to as an experience, this is nevertheless something quite usual in the case of a sexual idea, precisely because the retardation of puberty is a general characteristic of the organization. Every adolescent individual has memory traces which can only be understood with the emergence of sexual feelings of his own; and accordingly every adolescent must carry the germ of hysteria within him. There must obviously be concurrent factors as well, if this universal determining effect is to be limited to the small number of individuals [357] who actually become hysterics. Now analysis indicates that what is disturbing in a sexual trauma is evidently the release of affect; and experience teaches us to recognize hysterics as individuals of whom one knows in part that they have become *prematurely* sexually excitable owing to mechanical and emotional stimulation (masturbation), and of whom one can assume in part that a premature sexual release is present in their innate disposition. But premature *beginning* of sexual release or prematurely *intensified* sexual release are clearly equivalent. This factor is reduced to a quantitative one.

In what, however, does the significance of *prematureness* in sexual release reside? Here all the weight falls on the prematureness, for it cannot be maintained that sexual release in general is an occasion for repression; this would once again make repression into a process of normal frequency.

[6] *Disturbance of Thought by Affect*

We have not been able to reject [the fact] that the disturbance of the normal psychical process had two determinants: (1) that the sexual release was attached to a memory instead of to an experience, (2) that the sexual release took place *prematurely*. These two additions would bring about a disturbance which exceeds the normal amount but which is potentially present in the normal as well.

It is quite an everyday experience [*Erfahrung*] that the generation of affect inhibits the normal passage of thought, and in various ways. This happens, firstly, in that many paths of thought are forgotten which would ordinarily come into account – similarly, that is, to what occurs in dreams [p. 363 above]. Thus, for instance, it happened to me during the agitation

1 [See footnote 1, p. 377 above. The word at the beginning of this heading is in the plural in the MS., but is changed to singular in *Anf.*, 435.]

caused by a great anxiety that I forgot to make use of the telephone, which had been introduced into my house a short time before. The recent pathway succumbed in the affective state: *facilitation* – that is, what was *old established* – gained the upper hand.[1] This forgetting involves the disappearance of [the power of] selection, of efficiency and of logic in the passage [of thought], very much as happens in dreams. Secondly, [affect inhibits thought] in that without forgetting, pathways are followed which are ordinarily avoided: in particular, pathways leading to discharge, [such as] actions [performed] in the affect[ive state]. In conclusion, the affective process approximates to the uninhibited primary process.

A number of things are to be inferred from this. Firstly, that when
[358] there is a release of affect the releasing idea itself gains in intensity; secondly, that the main function of the cathected ego consists in avoiding fresh affective processes and in reducing the old affective facilitations. The position can only be pictured as follows. Originally, a perceptual cathexis, as inheritor of an experience of pain, released unpleasure; it [the cathexis] was intensified by the $Q\eta$ released, and then proceeded towards discharge along pathways of passage that were in part prefacilitated. After a cathected ego had been formed, 'attention' to fresh perceptual cathexes developed in the manner we know [pp. 360–1 and 362–3 above] and it [attention] followed with side cathexes the passage [of quantity] from the perception. By that means the release of unpleasure was quantitatively restricted, and its start was precisely a signal for the ego to set normal defence in action [p. 352 above]; this guarded against fresh experiences of pain, with their facilitations, developing so easily.[2] Nevertheless, the stronger the release of unpleasure, the harder was the task for the ego, which, with its side cathexes, can after all only provide a counterweight to the $Q\eta$s up to a certain limit, and is thus bound to permit a *primary passage* [of quantity] to occur.

Furthermore, the greater the quantity that is endeavouring to effect a passage, the harder for the ego is the activity of thought, which, as everything goes to show, consists in an experimental displacing of small $Q\eta$s [pp. 359 f. above and 391 ff. below]. 'Reflecting'[3] is a time-consuming activity of the ego's, which cannot occur when there are

1 [This reflects Ribot's law, which is linked in modern neuropsychology with the process of 'consolidation'.]

2 [This whole subject is discussed much more fully in Part III, p. 384 ff. below.]

3 ['*Das "Überlegen"*'. Cf. p. 357 above, where the word used is '*Nachdenken*', perhaps with a different sense, and there translated 'consideration'.]

strong *Qη*s in the level of affect. That is why when there is affect there is overhastiness, and a choice of pathways similar to the primary process.

Thus it is the ego's business not to permit any release of affect, because this at the same time permits a primary process. Its best instrument for this purpose is the mechanism of attention. If a cathexis releasing unpleasure were able to evade this, then the ego would come into action against it too late. Now this is precisely what happens in the case of the hysterical *proton pseudos*.[1] Attention is [normally] adjusted towards perceptions, which are what ordinarily give occasion for a release of unpleasure. Here, [however, what has appeared] is no perception but a memory, which unexpectedly releases unpleasure, and the ego only discovers this too late. It has permitted a primary process because it did not expect one.

However, there are other occasions too on which memories release [359]
unpleasure. Certainly this is quite normally so with fresh memories. If the trauma (experience of pain) occurs – the very first [traumas] escape the ego altogether – at a time when there is already an ego, there is to begin with a release of unpleasure, but simultaneously the ego is at work too, creating side cathexes.[2] If the cathexis of the memory is repeated, the unpleasure is repeated too, but the ego facilitations are there already as well; experience shows that the release [of unpleasure] is less the second time, until, after further repetition, it shrivels to the intensity of a signal acceptable to the ego. [Cf. pp. 351–2 above.][3] It is therefore only a question of the ego's inhibition not being absent at the *first*[4] release of unpleasure, of the process not occurring as a posthumous primary affective experience; and this [condition] is precisely fulfilled if, as in the case of the hysterical *proton pseudos*,[5] the memory is what first brings about the release of unpleasure.

The significance of one of the determinants which we have put forward [p. 381 above] and which were furnished by clinical experience would thus seem to be confirmed. *The retardation of puberty makes possible posthumous primary processes*.

1 [Translator's italics. See footnote 1, p. 377 above.]

2 [Cf. on this *Beyond the Pleasure Principle* (1920g), *RSE*, **18**, 29 f. – At the beginning of the next sentence the MS. has simply '*die Erbesetz*[*un*]*g*' ('the cathexis of the memory'). *Anf*., 438, reads '*die Besetzung der Erinnerungsspur*' ('the cathexis of the memory trace').]

3 [This topic is discussed at greater length on p. 404 ff. below.]

4 [This word is underlined in the MS. In *Anf*., 438, '*Unlustentbindung*' ('release of unpleasure') is emphasized instead.]

5 [Translator's italics.]

[PART III]
ATTEMPT TO REPRESENT NORMAL ψ PROCESSES

5 Oct. 95

[1]

[360] It must be possible for what I have termed the secondary processes to be explained on mechanical lines [p. 330 *n.* 1 above] through the effect produced by a constantly cathected mass of neurons (the ego) on others with changing cathexes. I will start with an attempt at a psychological representation of processes of this kind.

If I have on the one hand the ego and on the other hand perceptions[1] – that is, cathexes in ψ coming from φ (from the external world) – then I require a mechanism which causes the ego to follow the perceptions and to influence them. I find it [such a mechanism] in the fact that, according to my presuppositions, a perception invariably excites ω and thus gives rise to indications of quality.[2] To put it more accurately, it excites consciousness (consciousness of a quality) in ω,[3] and the discharge of the ω excitation will, [like] every discharge, furnish information to ψ, which is in fact the indication of quality.[4] I therefore put forward the suggestion that it is these indications of quality which *interest* ψ in the perception. [Cf. pp. 360–1 above.]

This would seem to be the mechanism of psychical attention.[5] I find it [361] hard to give a mechanical (automatic) explanation of its origin.[6] For that reason I believe that it is biologically determined – that is, that it has been left over in the course of psychical evolution because any

1 [In the MS.: '*W* (*Wahrnehm*[*un*]*gen*)'.]

2 [Cf. p. 350 above. *Anf.*, 439, misprints this as '*Quantitätszeichen*'.]

3 [So in the MS. *Anf.*, 439, wrongly prints '*W*'.]

4 [In the MS. the latter part of this sentence reads as follows: '*u*[*nd*] *die Abfuhr der ω Erreg*[*un*]*g wird jede Abfuhr eine Nachricht nach ψ liefern . . .*' This does not make sense, and *Anf.*, 439 (in addition to wrongly rendering the '*ω*' as '*Wahrnehmung*') silently omits the words '*jede Abfuhr*', leaving a coherent sentence meaning: 'and the discharge of the excitation of the perception will furnish information to ψ.' It seems probable that the true explanation of the crux is that the word '*wie*' ('like', 'as') was accidentally omitted by Freud before '*jede Abfuhr*'. This is confirmed by the almost identical passage on the same subject, *Anf.*, 410 (p. 350 above), in which the words '*wie von jeder Abfuhr*' ('as of every discharge') occur.]

5 [See Appendix C, p. 418 f. below.]

6 [But see p. 385 f. below. – Cf. also Appendix B (p. 414 f. below), as well as a remark of Breuer's in Section 2 of his contribution to *Studies on Hysteria* (1895*d*), in which he quotes a concept of Exner's (1894, 165), 'facilitation by attention [*attentionelle Bahnung*]', to account for the fact that in a working brain the 'intracerebral tonic excitation' is non-uniformly distributed (*RSE*, **2**, 174).]

other behaviour by ψ has been excluded owing to the generation of unpleasure.[1] The outcome of *psychical attention* is the cathexis of the same neurons which are bearers of the perceptual cathexis. This state has a prototype in the *experience of satisfaction* [p. 343 above], which is so important for the whole course of development, and in its repetitions, states of *craving* which have developed into states of *wishing* and states of *expecting*. I have demonstrated [Part I, Sections 16–18] that these states contain the *biological justification* of all thought. The psychical situation in them is as follows. Tension due to craving prevails in the ego, as a consequence of which the idea of the loved object (the *wishful* idea) is cathected. Biological experience has taught that this *idea*[2] should not be so strongly cathected that it might be confused with a perception, and that discharge must be postponed till the indications of quality appear from the *idea* as a proof that the *idea* is now real, a perceptual cathexis. If a perception arrives which is identical to the *idea* or similar to it, it finds its neurons *precathected* by the wish – that is, either all of them already cathected or a part of them – so far, in fact, as the agreement goes. The difference between the *idea* and the approaching perception then gives occasion for the process of thought, which reaches its end when the superfluous [i.e. unwanted] perceptual cathexes have been conveyed, along some pathway that has been found, into ideational cathexes. With this, *identity* is attained. [Cf. pp. 357–8 above.]

Attention thus consists in establishing the psychical state of expectation even for those perceptions which do not coincide in part with wishful cathexes. For it has in fact become important for a cathexis to be sent to meet all perceptions, since those that are wished for might be among them.[3] *Attention* is biologically justified; it is only a question of guiding the ego as to *which* expectant cathexis it is to establish and this purpose is served by the indications of quality.

The process of *adopting a psychical attitude* can perhaps be followed [362]
with still greater accuracy. Let us suppose that to begin with, the ego is not prepared in advance; a perceptual cathexis occurs and, after it, its indication of quality. The intimate facilitation between the two pieces of information will further increase the perceptual cathexis and now a

1 [A strictly evolutionary causation would not be attributable to the generation of unpleasure so much as to what the unpleasure indicates, namely that the organism is in danger (i.e. that its reproductive potential is reduced). See Editors' footnote 1, p. 330 above. Cf. *Inhibitions, Symptoms and Anxiety* (1926*d*), *RSE*, **20**.]

2 [In the MS. '*V*' (*Vorstellung*) is doubly underlined, as it is also in the rest of this paragraph.]

3 [The last clause is omitted in *Anf*., 440. The MS. reads: '*da sich die gewünschten darunter befinden könnten*.']

cathexis of the perceptual neurons with attention will result. The next perception of the same object will (in accordance with the second law of association[1]) lead to a fuller cathexis of the same perception and only this will be the perception that is serviceable psychically.

(This part of the description already yields a highly important thesis. The first time a perceptual cathexis occurs its intensity is slight, with little Q; the second time, when there is a ψ precathexis, it is quantitatively greater. Now, judgement on the quantitative characteristics of the object is not in principle changed by attention. Consequently, the external Q of objects cannot be expressed in ψ by psychical $Q\eta$. Psychical $Q\eta$ means something quite different, which is not represented in reality, and external Q is in fact expressed in ψ by something different – by complexity of cathexes [pp. 339–40 above]. By that means, however, external Q is kept off from ψ.)

The following description is still more satisfying. As an outcome of biological experience, ψ attention is constantly directed to the indications of quality. These take place, therefore, on precathected neurons and with sufficiently great quantity. The information of quality, thus strengthened, strengthens the perceptual cathexes by its facilitation; and the ego has learnt to make its cathexes of attention follow the passage of this associative movement from the indication of quality to the perception. By this means it is led to cathect precisely the right perceptions or their environment. Indeed, if we assume that it is the same $Q\eta$ from the ego which travels by the facilitation from the indication of quality to the perception, we have actually explained the cathexis of attention mechanically (automatically) [p. 384 above]. Thus attention leaves the indications of quality and turns to the now hypercathected perceptual neurons [pp. 355–6].

Let us suppose that for some reason the mechanism of attention has failed; then the ψ cathexis of the perceptual neurons will not occur and the Q which has reached them will be transmitted (purely associatively) in the direction of the best facilitations, so far as the relations between
[363] the resistances and the quantity of the perceptual cathexis permit. [Cf. p. 348 above.] This passage [of quantity] would probably soon come to an end, since the Q divides up and forthwith, in some nearby neuron, becomes too small to flow any further. Under certain conditions the passage of the perceptual quantity[2] may subsequently [*nachträglich*] excite

1 ['Association by similarity.' Freud originally wrote '*ersten*' ('first') and afterwards corrected it to '*zweiten*' ('second'). The first law, 'Association by contiguity', was introduced on p. 343 f. above.]

2 ['*Wq*' in the MS. *Anf.*, 442, expands this into '*die an der Wahrnehmung haftenden Quantitäten* (*Wq*)' ('the quantities attached to the perception (*Wq*)').]

attention, or again, it may not. In that case it ends unobserved in the cathexis of some neighbouring neuron, of whose fate we know nothing. Such is a passage of perception without attention, as it must occur countless times every day.[1] It cannot proceed far, as analysis of the process of attention will show, and from this we can infer the smallness of perceptual quantity.

If, however, a perceptual [neuron][2] has received its cathexis of attention, a number of things may happen, among which two situations may be stressed – those of *ordinary thought* and of merely *observing thought*. The latter case appears to be the simpler; it corresponds more or less to the state of an investigator who has made a perception and asks himself: what does this mean? What does this lead to? He then proceeds in this way. (For the sake of simplicity, however, I must now replace the cathexis of the complex perception by that of a single neuron.)[3] The perceptual neuron is hypercathected; the quantity composed of Q and $Q\eta$[4] flows away in the direction of the best facilitations and, in accordance with resistance and quantity, will surmount a few barriers and will cathect some fresh, associated neurons; other barriers it will not surmount, because the quotient falling to their share lies below the threshold.[5] It is certain that more and remoter neurons are cathected now than when there is a merely associative process without attention. Here too the current will [364] eventually end in certain terminal cathexes or in a single one. The outcome of the attention will be that instead of the perception one or several *mnemic* cathexes appear (linked with the initial neuron by association).

It will be assumed, for simplicity's sake, that it is a single *mnemic image*.[6] If this could again be cathected (with attention) from ψ, the

1 [Cf. p. 397 below. An extremely similar account can be found in *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 530–2. It is there described as a 'preconscious' train of thought – a term introduced by Freud in the letter to Fliess of December 6, 1896 (p. 261 above).]

2 ['*W*' in the MS. (neuter by deduction). *Anf.*, 442, expands this into '*das System W*', as though mistakenly reading it as '*ω*'.]

3 [See Editors' footnotes: pp. 344 *n.* 3 and 353 *n.* 2 above.]

4 ['*Die aus Q u*[*nd*] *Qη zusammengesetzte Quantität*' in the MS. This is expanded in *Anf.*, 442, into '*die aus äusserer und psychischer Quantität (Q und Qη) zusammengesetzte Quantität*' ('the quantity composed of external and psychical quantity (*Q* and *Qη*)').]

5 [In *Anf.*, 442, the words represented here by 'and will cathect some fresh, associated neurons; other barriers it will not surmount' are omitted, upsetting the sense. The missing German passage reads in the MS.: '*u*[*nd*] *neue associierte N besetzen andere Schranken nicht überwinden*.']

6 [This sentence is ungrammatical in the MS. and has been altered in *Anf.*, 443, without affecting the sense.]

game would be repeated: the Q would once more start flowing[1] and, along the pathway of best facilitation, would cathect (*awaken*) a fresh *mnemic image*. Now it is clearly the intention of *observing thought* to become acquainted to the furthest possible extent with the pathways leading from the perception;[2] in this manner, indeed, knowledge of the perceptual object is to be made exhaustive. It will be noted that the method of thought here described leads to *cognition*.[3] For that reason a ψ cathexis is once more required for the mnemic images that are reached, but also a mechanism which will lead that cathexis to the right points. How else are the ψ neurons in the ego to know where the cathexis is to be directed to? A mechanism of attention such as that described above again presupposes, however, indications of quality. Do these arise during the associative passage [of quantity]? Not as a rule, according to our presuppositions. They can, however, be obtained by means of a fresh contrivance of the following description. Indications of quality come about normally only from perceptions; it is thus a question of obtaining a perception from the passage of $Q\eta$. If a [motor] discharge were linked to the passage of $Q\eta$ (in addition to the [mere] circulation), then, like every movement, it [the discharge] would furnish [kinaesthetic] information of the movement [p. 343 above]. After all, indications of quality themselves are only[4] information of discharge [p. 350] (of what kind [we may learn][5] later perhaps). Now it may happen that during the passage of Q[6] a motor neuron is cathected as well, which then discharges $Q\eta$ and furnishes an indication of quality. It is a question, however, of receiving discharges of this kind from all cathexes.[7] They are not all motor, and for this purpose, therefore, they must be brought into a secure facilitation with motor neurons.

1 [Here and in several other places (e.g. p. 337 above) the figurative impression of Q flowing as a liquid is created. The actual process is of course a propagation of Q. (See Appendix C below.)]

2 [In the MS.: '*von W*'. Once again (cf. pp. 386–7 above) *Anf.*, 443, expands this into '*vom System W*', under the impression that Freud wrote '*ω*'.]

3 ['*Erkennen*.' See Editors' footnote 3, p. 352 above.]

4 ['*nur*' in the MS. Omitted in *Anf.*, 443.]

5 [The verb is missing in the MS. *Anf.*, 443, replaces it with '*besprechen wir*' ('we may discuss').]

6 [The MS. reads 'Q', which *Anf.*, 443, emends to $Q\eta$.]

7 [The sense possibly implies a direct, efferent (not only a kinaesthetic, afferent), motor discharge. See Editors' footnote 4, p. 350 f. above.]

This purpose is fulfilled by *speech association*.[1] This consists in the [365]
linking of ψ neurons with neurons which serve sound presentations[2] and themselves have the closest association with motor speech images. These associations have an advantage of two characteristics over the others: they are limited[3] (few in number) and exclusive. In any case, from the sound image the excitation reaches the [motor] word image and from it reaches discharge. Thus, if the mnemic images are of such a kind that a part-current can go from them to the sound images and motor word images, then the cathexis of the mnemic images is accompanied by information of discharge, which is an indication of quality and also accordingly an indication of the consciousness of the memory.[4] If now the ego precathects these word images as it earlier did the images of ω[5] discharge [p. 384 ff. above], then it will have created for itself the mechanism which directs the ψ cathexis to the memories emerging during the passage of *Qη̇*.[6] This is *conscious, observing thought*.

In addition to making cognition possible, speech association achieves something else, of great importance. As we know, the facilitations between the ψ neurons constitute '*memory*', the representation of all the influences which ψ has experienced from the external world. Now we observe that the ego itself puts in hand cathexes of the ψ neurons as well, and sets going passages [of quantity] which must certainly also leave [366]
facilitations behind them as traces. ψ, however, has no means of distinguishing these results of thought processes from the results of perceptual processes. It may perhaps be possible to cognize and reproduce

1 [In the passages that follow, Freud stated for the first time his theory of the important part played by speech in psychical function and, in particular, in the distinction between unconscious and preconscious processes (conceptualized in modern neuropsychology as 'non-declarative' and 'declarative' processes). He alluded to this theory very briefly in *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 514 and 551 f., and again in his paper on the 'Two Principles of Mental Functioning' (1911*b*), ibid., **12**, 218. But his full development of the theme was in his metapsychological paper on 'The Unconscious' (1915*e*), ibid., **14**, 177 ff. He returned to it once again in *The Ego and the Id* (1923*b*), ibid., **19**, 17, and as late as in his posthumous *Outline* (1940*a* [1938]), ibid., **23**, 146 f. His interest in the question, however, evidently went back to his study of aphasia, on which he had published his monograph only four years before the present work. The passage from that monograph (1891*b*; *NSW*, **4**, Chapter VI) which relates most closely to metapsychological problems is included as an Appendix to the paper on 'The Unconscious' mentioned above (*RSE*, **14**, 186 ff.). See also Appendix C, p. 417 ff. below.]

2 ['*Vorstellungen*' is here translated by the more technical 'presentations' instead of, as elsewhere in this work, by 'ideas'. See *RSE*, **24**, 94–8.]

3 ['*geschlossen*', literally 'closed'.]

4 [In the MS.: '*Bewzeichen der Er*'. We follow *Anf.*, 444, which expands this to '*Bewusstseinszeichen der Erinnerung*'.]

5 [So in the MS. *Anf.*, 444, reads: '*Wahrnehmung*' ('perception'), as though it were a '*W*'.]

6 [This answers the questions raised on p. 388 above.]

perceptual processes by their association with ω discharges;[1] but all that remains of the facilitations made by thought is the outcome, not a *memory*. The same thought facilitation may have come about owing to one intense process or ten less forcible ones. The *indications of speech discharge* help, however, to make good this lack; they put thought processes on a level with perceptual processes, lend them reality and *make memory of them possible*. [Cf. p. 360 above, but also p. 402 below.]

The biological development of this extremely important [kind of] association also deserves consideration. Speech innervation is originally a path of discharge[2] for ψ, operating like a safety-valve, for regulating oscillations in $Q\eta$; it is a portion of the path to *internal change*, which represents the only discharge till the *specific action* has been found. [For all this, cf. pp. 342–3 above.] This path acquires a secondary function from the fact that it draws the attention of the helpful person (usually the wished-for object itself) to the child's longing and distressful state; and thereafter it serves for *communication* and is thus drawn into the specific action. At the start of the function of judgement, when the perceptions, on account of their possible connection with the wished-for object, are arousing interest, and their complexes (as has already been shown [pp. 354 and 356–7]) are dissected into an unassimilable[3] component (the thing) and one known to the ego from its own experience (attribute, activity) – what we call *understanding* – [at this point] two links emerge in relation to utterance by speech. In the first place, there are objects – perceptions – that make one *scream*, because they arouse pain; and it turns out as an immensely important fact that this association of a sound (which arouses motor images of one's own as well) with a perceptual [image], which is composite apart from this, emphasizes that object as a hostile one and serves to direct attention to the perceptual [image]. When otherwise, owing to pain, one has received no good indication of the quality of the object, the *information of one's own scream* serves to
[367] characterize the object. Thus this association is a means of making memories that arouse *unpleasure* conscious and objects of attention: the first class of *conscious memories* has been created. Not much is now needed in order to invent speech. There are other objects, which constantly produce certain sounds – in whose perceptual complex, that is, a sound plays a part. By virtue of the trend towards *imitation*, which emerges

1 [Once again *Anf.*, 444, reads '*Wahrnehmung*' instead of 'ω', as in the MS.]

2 ['*Abfuhrbahn*' in the MS. *Anf.*, 444, omits the '*bahn*' ('path').]

3 [I.e. one that cannot be 'assimilated' in the sense of 'likened'. The equivalent terms used in an earlier passage (p. 357 above) were 'non-comparable' and 'disparate'.]

during judging [p. 358 f. above], it is possible to find the information of movement attaching to this sound image. This class of memories, too, can now become conscious. It now still remains to associate intentional sounds with the perceptions; after that, the memories when the indications of sound discharge are observed become conscious like perceptions and can be cathected from ψ.

Thus we have found that it is characteristic of the process of *cognitive* thought that during it attention is from the first directed to the indications of thought discharge, to the indications of speech. As is well known, indeed, what is called conscious thought takes place to the accompaniment of slight motor expenditure.

The process of following the passage of Q through an association can accordingly be continued for an indefinite length, usually as far as 'completely familiar' terminal elements of the association. The fixing of this pathway and of its terminal halting points then comprises the 'cognition' of the perception, which may be a new one.

We should be glad, however, to know something quantitative about this process of cognitive thought. Here, indeed, the perception is hypercathected in comparison with the naive associative process. The process itself consists in a displacement of $Q\eta$ regulated by the association with indications of quality; the ψ cathexis is renewed at every halting point and finally a discharge takes place from the motor neurons of the speech path. We ask ourselves now whether much $Q\eta$ is lost to the ego during this process or whether the expenditure in thought is a relatively small one. A pointer to an answer to this question is given by the fact that the current of speech innervations during thought is obviously very small. We do not really speak, any more than we really move when we imagine a motor image. But the idea and the movement only differ quantitatively, as we have learnt from experiments on thought-reading.[1] If thought is intense, no doubt people even speak out loud. But how is it possible to bring about such small discharges, since, after all, small $Q\eta$s cannot flow and large ones level themselves off *en masse*[2] through the motor neurons?[3]

It is probable that in the process of thought the displacement quantities too are not large. In the first place, the expenditure of large $Q\eta$ is a loss for the ego which has to be restricted as far as possible; for the $Q\eta$ is earmarked for the exacting specific action [pp. 321 and 348 above]. In [368]

1 ['*Gedankenlesen*' means mind-reading but the sense here seems to imply 'lip-reading'.]

2 [Translator's italics.]

3 [Cf., for this and what follows, p. 359 f. above.]

the second place, a large $Q\eta$ would pass along several associative pathways simultaneously and leave no time for thought cathexis and would also cause a large expenditure. No doubt, therefore, the current of $Q\eta$ during the thought process must be small. Nevertheless,[1] on our hypothesis, perception and memory during thought must be hypercathected more strongly than during simple perception. Furthermore, there are, of course, different intensities of attention, which we can only translate as different increases of the cathecting $Q\eta$. In that case, observant following would be more difficult precisely when attention was stronger – which is so inexpedient that we cannot suppose it to be the case.

Here we have two apparently opposing requirements: strong cathexis and weak displacement. If we want to reconcile the two, we arrive at the hypothesis of what is, as it were, a *bound state*[2] in the neuron, *which, though there is a high cathexis, permits only a small current*. This hypothesis can be made more plausible if we reflect that the current in a neuron is obviously influenced by the cathexes surrounding it. Now the ego itself is a mass like this of neurons which hold fast to their cathexis – are, that is, in a bound state; and this, surely, can only happen as a result of the effect they have on one another. We can therefore imagine that a perceptual[3] [neuron] which is cathected with attention is as a result temporarily, as it were, [taken up][4] into the ego and is now subject to the same binding of its $Q\eta$ as are all the ego neurons. If it is cathected more strongly, then the quantity of current may in consequence be diminished, not necessarily increased.[5] We may perhaps suppose that as a result of this binding precisely the external Q remains free to flow while the cathexis of attention is bound; a relation which need not, of course, be an invariable one.

This bound state, which combines high cathexis with small current, would thus characterize processes of thought mechanically. It is possible
[369] to conceive of other processes in which the current runs parallel with the cathexis – processes with uninhibited discharge.

1 ['*dennoch*' in the MS. *Anf.*, 447, misreads '*demnach*' ('accordingly').]

2 [This has already been touched on above, on p. 360.]

3 ['*ein* [neuter] *W*' in the MS. *Anf.*, 447, expands this, perhaps rightly, to '*Wahrnehmungsneuron*' ('perceptual neuron'); a neuter '*W*' usually stands for '*Wahrnehmungsbild*' ('perceptual image'), cf. pp. 355–6 above. *GW*, **Nachtr.**, 459, also follows *Anf.*]

4 [The verb is missing in the MS. *Anf.*, 447, supplies '*aufgenommen*'.]

5 [There is a question mark at this point in *Anf.*, 447, of which there is no trace in the MS.]

I hope the hypothesis of a bound state of this kind will turn out to be mechanically tenable.[1] I should like to throw some light on the psychological consequences of this hypothesis. The hypothesis appears at first to suffer under an internal contradiction. If the [bound] state consists in only small *Q*s being left for displacement when there is a cathexis of this kind, how can it [the bound state] draw fresh neurons into it – that is, cause large *Q*s to travel into fresh neurons? And, carrying the same difficulty further back, how can an *ego* compounded in this way have been able to develop at all?

Thus we find ourselves quite unexpectedly before the most obscure problem: the origin of the 'ego' – that is, of a complex of neurons which hold fast to their cathexis, a complex, therefore, which is for short periods at a constant level [pp. 347–8 above].[2] A genetic treatment will be the most instructive.[3] The ego consists originally of the nuclear neurons, which receive endogenous $Q\eta$ through paths of conduction [p. 340] and discharge it along the pathway to internal change [p. 342]. The experience of satisfaction has brought about an association between this nucleus and a perceptual image (the wishful image) and information of a movement ([information of] the reflex portion of the specific action) [p. 343]. The education[4] and development of this original ego takes place in a repetitive state of craving, in *expectation* [p. 385]. It [the ego] learns first that it must not cathect the motor images, so that discharge results, until certain conditions have been fulfilled from the direction of the perception. It learns further that it must not cathect the wishful idea beyond a certain amount since otherwise it would deceive itself in a hallucinatory manner [pp. 351–2]. If, however, it respects these two barriers and directs its attention to the new perceptions, it has a prospect of attaining the satisfaction it is seeking. It is clear, therefore, that the barriers which prevent the ego from cathecting the wishful image and the motor image beyond a certain amount are the ground for an accumulation of $Q\eta$ in the ego, and compel it, perhaps, to transfer its $Q\eta$ within certain limits to the neurons accessible to it.

1 [This hypothesis is a fundamental premise in modern computational neuroscience. The Helmholtzian free-energy principle assumes that the brain uses internal models of reality to predict ('bind') sensory input, and suggests that neuronal activity (and connectivity) tries to minimize the ensuing prediction-error. The amount of 'free energy' is an information theory quantity that, mathematically, plays the same role as free energy in statistical thermodynamics. The amount of 'bound' energy in neuronal simulations can accordingly be statistically quantified. (See Carhart-Harris & Friston, 2010.)]

2 [The '*sind*' at the end of this sentence in *Anf.*, 448, is not in the MS.]

3 [For what follows, cf. p. 347 ff. above.]

4 [The MS. reads quite clearly '*Entzieh*[*un*]*g*' ('withdrawal'). *Anf.*, 448, emends this, very plausibly, to '*Erziehung*' ('education' or 'upbringing'). Cf. the use of this word below, on p. 396.]

[370] The hypercathected nuclear neurons abut in the last resort on the paths of conduction from the interior [of the body] which have become permeable owing to being continually filled with *Qη* [p. 341 above]; and they [the nuclear neurons], being a continuation of these [paths of conduction], must likewise remain filled. The *Qη* in them will flow away for a distance proportional to the resistances met with in its pathway, till the next resistances are greater than the quotient of *Qη* available for the current. Thereafter, the whole cathectic mass is in equilibrium, held on one side by the two barriers against motility and [hallucinatory] wishing and on the other side by the resistances of the furthest neurons, and towards the interior by the constant pressure of the paths of conduction. Inside this ego structure the cathexis will by no means be everywhere equal; it need only be equal proportionately – that is, in relation to the facilitations. [Cf. p. 362.]

If the level of cathexis in the ego nucleus rises, the extent of the ego will be able to expand its range; if it [the level] sinks, the ego will narrow concentrically. At a given level and a given extent of the ego there will be nothing to prevent displacement being possible within the area of cathexis.

It only remains to enquire about the origin of the two barriers which guarantee the constant level of the ego and, in particular, of that against motor images, which prevents discharge. Here we are at a point decisive for our view of the whole organization. All we can say is that when this barrier was not yet in existence and when motor discharge took place along with the wish, the expected pleasure regularly failed to appear and the continuance of the release of the endogenous stimuli finally evoked unpleasure. Only this threat of *unpleasure*, which became attached to premature discharge, can represent the barrier in question. Afterwards, in the course of development, facilitation took over a part of the task. But it still remains a fact that the *Qη* in the ego does not cathect motor images immediately, because *the consequence would be a release of unpleasure*.

Everything that I call a *biological acquisition* of the nervous system is in my opinion represented by a *threat of unpleasure* of this kind,[1] the effect of which consists in the fact that those neurons which lead to a release of unpleasure are *not*[2] cathected. This is *primary defence* [p. 347 above], an understandable consequence of the original trend of the nervous system [p. 320]. Unpleasure remains the only means of

1 [This contradicts the earlier claim to ignorance of the biological value of consciousness (cf. p. 336 *n.* 3 above). See Editors' footnote 1, p. 385 above.]

2 [In the MS. this word is doubly underlined.]

education. How *primary defence*, non-cathexis owing to a threat of unpleasure, is to be represented mechanically – this, I confess, I am unable to say.

From this point onwards, I shall venture to leave unanswered the [371] question of finding a mechanical representation of biological rules such as this; I shall be content if henceforth I am able to remain faithful to a clearly demonstrable course of development. A second biological rule, abstracted from the process of expectation [p. 385 f. above], must no doubt be that attention is to be directed to the indications of quality, because these belong to perceptions which may lead to satisfaction, and that one is then to allow oneself to be led from the indication of quality to the perception that has emerged. In short, the mechanism of attention must owe its origin to a biological rule of this kind; it [this mechanism] will regulate the displacement of the ego cathexes.

It may now be objected that a mechanism like this with the help of the indications of quality is redundant. The ego might have learnt biologically itself to cathect the perceptual region in states of expectation, instead of only being induced to make this cathexis by the indications of quality. There are, however, two things to be said here in justification of the mechanism of attention. (1) The region of the indications of discharge from ω is obviously a smaller one, comprises fewer neurons, than that of the perceptions – that is, of the whole pallium of ψ which is connected with the sense organs [p. 340 above];[1] so that the ego saves an extraordinarily large expenditure by keeping the indications of discharge[2] cathected instead of the perceptions. And (2) the indications of discharge or indications of quality are first and foremost also indications of reality, which should precisely serve the purpose of distinguishing real perceptual cathexes from wishful cathexes. Thus we cannot evade the mechanism of attention. But it consists, in every case, in the ego *cathecting* those *neurons* in which a cathexis has already appeared.

For the ego, then, *the biological rule of attention* runs: *If an indication of reality appears, then the perceptual cathexis which is simultaneously present is to be hypercathected.*

This is the second biological rule. The first one was that *of primary defence*.[3]

1 [Cf. Editors' footnotes above: pp. 350 f. *n*. 4 and 388 *n*. 7.]

2 ['*Abfuhrz*' in the MS. (as five lines above and just below). *Anf*., 450, overlooking the '*z*', reads simply '*Abfuhr*' ('discharge').]

3 [See p. 394 above. 'That of' is omitted in *Anf*., 451.]

[2]

From what has been arrived at so far, a few general hints may also be gathered towards giving a mechanical representation [of psychical processes] – such as the first one was, to the effect that external quantity cannot be represented by $Q\eta$, psychical quantity [p. 386 above]. For it
[372] follows from the description of the ego and of its oscillations [p. 394] that the height of the level [of its cathexis], too, has no relation to the external world, that a general lowering or raising of it makes no change (normally) in the picture of the world. Since the picture of the external world is based on *facilitations*,[1] that means that general oscillations of level make no change in the facilitations. A second principle has already been mentioned: namely, that when the level [of cathexis] is high, small quantities can be displaced more easily than when it is low [p. 392]. These are some individual points which must be borne in mind in arriving at the characteristics of neuronal motion, which is still quite unknown to us.[2]

Let us go back now to the description of the observing or *cognitive* process of thought [p. 387 ff. above], which is distinguished from the process of expectation by the fact that [in the former] the perceptions do not light upon wishful cathexes. Thus in that case the ego is made attentive by the first indications of reality as to which region of perception is to be cathected. The passage of association of the Q brought along with them [by the perceptions] occurs over precathected neurons and the $Q\phi$,[3] which is displacing itself, can flow on again each time.[4] During this passage [of association] the indications of quality (of speech) are generated, as a result of which the passage of association becomes conscious and capable of being reproduced.

Here now, once again, the benefit of the indications of quality might be questioned.[5] What they achieve [it might be argued] is after all only to

1 [I.e. facilitations constitute the 'representational' fabric of mental life.]

2 [There is a transverse line here in the MS., unmarked in *Anf.*, 451. A similar line separated sections [1] and [2] (pp. 395–6 above) in the MS. – Regarding ignorance of the characteristics of neuronal motion, see Appendix C below.]

3 [The quantity from the system ϕ, i.e. originating from the external world (p. 327 f. above). The words in brackets in *Anf.*, 451, '*Quantität der ϕ-Neuronen*', are not in the MS. The term is written out in full, '*ϕ-Quantität*', on p. 405 below.]

4 [I.e. from one precathected neuron to another. This seems a probable explanation of the words: '*wird jedesmal wieder flott*' (*Anf.*, 451). Cf. p. 387 above.]

5 [In what follows, the pleasure–unpleasure dimension of quality is disregarded. Cf. the pivotal role of 'signal' affects in Freud (1926*d*), *RSE*, **20**.]

cause the ego to send out cathexis to the point at which a cathexis emerges in the passage [of association]. They [the indications of quality] do not, however, provide this cathecting *Qη* themselves but at most only a contribution to it. But, if so, the ego can cause its cathexis to travel along the passage of the *Q* without any such support.

That is no doubt true, but paying regard to the indications of quality is nevertheless not redundant. For it must be emphasized that the biological rule of attention stated above is abstracted from perception [p. 395 above] and applies in the first instance only to indications of reality. [373] Indications of discharge through speech are also in a certain sense indications of reality – but of thought reality not of external reality,[1] and in their case a rule of this kind has not by any means come into effect, because no constant threat of unpleasure would be attached to a breach of it. The unpleasure through neglecting cognition is not so glaring as that from ignoring the external world, though at bottom they are one and the same. Thus there is in fact also[2] an *observing process of thought* in which indications of quality are either not, or only sporadically, aroused, and which is made possible by the fact that the ego follows the passage [of association] automatically with its cathexes. This process of thought is in fact far the more frequent, without being abnormal; it is our ordinary thought, unconscious, with occasional *intrusions*[3] into consciousness – what is known as conscious thought with unconscious intermediate links, though these can be made conscious. [Cf. p. 387 above.]

Nevertheless, indications of quality are of indisputable utility for thought. In the first place, indeed, the awakened indications of quality strengthen the cathexes in the passage [of association] and ensure the

1 [This seems to be the first appearance of a distinction which, after an interval of many years, played an increasing part in Freud's theories. It emerged prominently in the last of the essays in *Totem and Taboo* (1912–13*a*), *RSE*, **13**, 146–7, and soon afterwards it was introduced (in 1914) into a sentence in the closing pages of *The Interpretation of Dreams*, ibid., **5**, 554. In both these cases the distinction was between 'psychical' and 'factual' reality. In later discussions the latter term was altered to 'material': for instance, in the *Introductory Lectures* (1916–17*a*), ibid., **16**, 325, in the paper on 'The "Uncanny"' (1919*h*), ibid., **17**, 237–43, and in 'Dreams and Telepathy' (1922*a*), ibid., **18**, 207–8. The distinction appears finally in *Moses and Monotheism* (1939*a*), ibid., **23**, 70 f., where, as in this earliest instance, the second word used was 'external'. It may be thought that there is some similarity between this distinction and that between 'historical' and 'material' truth, which is also fully considered in *Moses and Monotheism*, ibid., 116 ff.; and this, too (as is made plain in an Editors' footnote, ibid., 118 *n.*), goes back to writings of Freud's contemporary with the present one.]

2 ['*auch*' in the MS. Omitted in *Anf*., 452.]

3 ['*Einfälle*.' '*Einfall*' often stands for 'an idea occurring to one' and may sometimes be rendered 'association'. See, however, an Editors' footnote to Lecture III of the *Introductory Lectures*, *RSE*, **15**, 42–3 *n*. See also ibid., **24**, 63–4.]

automatic attention which is evidently linked – we do not know how – to the emergence of cathexis. In the next place (and this seems more important) attention to the indications of quality ensures the impartiality of the
[374] passage [of association]. For it is very difficult for the ego to put itself into the situation of mere '*investigation*'. The ego almost always has purposive or wishful cathexes, whose presence during investigation, as we shall see [p. 400 below], influences the passage of association and so produces a false knowledge of perceptions. Now there is no better protection against this falsification of thought than if an ordinarily displaceable $Q\eta$ is directed to [? by] the ego to a region which cannot manifest a diversion such as this of the passage [of association].[1] There is only a single such expedient – if, namely, attention is directed to the indications of quality, which are not purposive ideas, whose cathexis, on the contrary, by contributions to the quantity of cathexis, lays greater emphasis on the passage of association.

Thus thought accompanied by a cathexis of the indications of thought reality or of the indications of speech is the highest, securest form of cognitive thought process.

In view of the undoubted utility of arousing the indications of thought, we may expect to find contrivances to ensure their arousal. Indications of thought are not, indeed, generated spontaneously like indications of reality, without the participation of ψ. Here observation tells us that these contrivances do not apply for all cases of thought process as they do for investigating thought. The necessary condition for indications of thought being aroused at all is, of course, their being cathected by attention; they come about in that case by virtue of the law that, when two neurons are linked and simultaneously cathected, conduction [between them] is favoured [pp. 343–4 above]. Yet the *attraction* produced by the precathexis of the indications of thought has only a certain degree of force in fighting against other influences. Thus, for instance, every other cathexis in the neighbourhood of the passage [of association] (purposive cathexes, affective cathexes) will compete with it and make the passage [of association] unconscious. A similar effect (as is confirmed by experience) will be brought about by Qs in passage[2] of considerable magnitude,

1 [This obscure sentence reads in the MS.: '*Es giebt nun keinen besseren Schutz gegen diese Denkfälsch*[*un*]*g als wenn dem Ich eine sonst verschiebbare Qη auf eine Region gerichtet wird, die eine solche Ablenk*[*un*]*g des Ablaufes nicht äussern kann*.' The only doubtful word is the one immediately preceding '*Ich*'. This is almost certainly '*dem*', though there is a possible sign of its having been altered from '*im*' to '*dem*' or *vice versa*. *GW*, **Nachtr.**, 464, puts '*dem Ich*' (with the editorial comment we have here) but *Anf*., 452–3, alters '*dem Ich*' into '*im Ich*' and adds after '*äussern*' '(i.e. *hervorrufen*)' '(i.e. evoke)'.]

2 ['*Ablaufsq*' in the MS.]

which produce a larger current and so accelerate the whole passage [of association]. The common assertion that 'something happened in one so quickly that one did not notice it' is no doubt quite correct. And it is [375] universally recognized that affects can interfere with the arousing of indications of thought.

From this we arrive at a fresh thesis for the mechanical representation of psychical processes: namely, that the passage [of association], which is not altered by the height of level [of cathexis], can be influenced by the *Q* itself that is *in flow. In general, a large Q takes different pathways in the network of facilitations from a small one.* There is no great difficulty, I think, in illustrating this:

Every barrier has a threshold value, below which no *Q* at all can pass – let alone, therefore, a quotient of it. A *Q* as small as this will further divide up [p. 348 above] along two other pathways, for whose facilitation the *Q* is sufficient. If now the *Q* increases, the first pathway will come into account and will help on its quotients; and now too, maybe,[1] cathexes on the further side of what is now a surmountable barrier will be able to make themselves felt. Yet another factor, indeed, may become important. We may perhaps assume that not all of a neuron's pathways are equally[2] receptive to *Q*, and we may describe this difference as *breadth of pathway.* Breadth of pathway is in itself independent of resistance, which indeed can be altered by *Q*s in passage whereas the breadth of pathway remains constant.[3] If we assume that with an increasing *Q* a pathway is opened which can bring its breadth into effect, then one can perceive the possibility of the passage of *Q* being fundamentally altered by an increase in the *Q* in flow. Everyday experience seems to give express support to precisely this conclusion.

The arousing of indications of thought seems, then, to be linked to the passage of small *Q*s. This is not to assert that any other passage [of *Q*] is bound to remain *unconscious*, since the arousing of indications of speech is not the only method of arousing consciousness.

How, then, can we perhaps give a clear picture of thought that becomes conscious intermittently, of sudden intrusions [into consciousness (p. 397 above)]? After all, our ordinary purposeless thought, though it is accompanied by precathexis and automatic attention, attaches no importance

1 ['*etwa*' in the MS. Omitted in *Anf*., 454.]

2 ['*gleich*' in the MS. Omitted in *Anf*., 454.]

3 [What is suggested here seems to be something in the nature of inherent variability in and between synapses. It is important to remember that nineteenth-century neuroscientists had no inkling of the different types of neurotransmitter (and neuromodulator) and receptor, which are of course independent of differences in synaptic permeability.]

to indications of thought. It has not been shown, biologically, that they are indispensable for the process. Nevertheless, they usually emerge (1) if the smooth passage [of quantity] has reached an end or has come up against an obstacle, and (2) if it has aroused an idea which, for other
[376] reasons, calls up indications of quality – that is, consciousness. At this point the discussion may be broken off.

[3]

There are obviously other kinds of thought process which, instead of the disinterested aim of cognition, have another, practical, aim in view. The state of expectation, which was the starting point of all thought [p. 385 above], is an example of this second kind of thought. Here a wishful cathexis is firmly retained, while alongside of it a second, perceptual, cathexis which emerges is followed with attention.[1] But in this case the intention is not to discover in general where it will lead to, but to discover along what paths it will lead to the activation of the wishful cathexis which has meanwhile been firmly retained. This kind of thought, biologically the earlier one, can easily be represented in accordance with our premises.

Let *V*+ be the wishful idea which is kept specially cathected and let *W* be the perception which is to be followed.[2] Then the result of the cathexis of *W* with attention will be in the first place that the $Q\phi$ [quantity from the system ϕ (p. 396 above)] will pass in the direction of the best facilitated neuron, *a*; from there it would go on once more in the direction of the best facilitation, and so on. The trend towards going in the direction of the best facilitation will, however, be interrupted by the presence of
[377] *side cathexes*.[3] Supposing that three pathways lead from *a*, to *b*, *c*, and *d*

1 [This situation of a firmly held cathexis on the one hand and a simultaneous travelling cathexis of attention on the other figures prominently in different forms throughout the 'Project'. (See, for instance, Sections 15–18 of Part I and Section 1 of Part III.) In more than one passage (e.g. pp. 385 f. and 397 above) the travelling cathexis is undirected and, as in the first sentence of this section, 'disinterested'. It is difficult not to see in this a kinship with what was to be the earliest form of 'free association' in the technique of psychoanalysis – namely the form in which some specific parapraxis or element of a dream is held as a starting point, while another part of the mind embarks on a stream of associations. There are, indeed, some remarks which bring out this very point in Lecture VI of the *Introductory Lectures* (1916–17*a*), *RSE*, **15**, 94 ff.]

2 ['*V*' stands for '*Vorstellung*' ('idea') and '*W*' for '*Wahrnehmung*' ('perception'). The MS. has '*V*+' here, but '+*V*' at all the later appearances of the symbol. *Anf.*, 455, has '–*V*' here, but '+*V*' everywhere else. Cf. also p. 355 *n*. 4 above.]

3 [In *Anf.*, 455, the last two sentences have been telescoped owing to a haplography of the copyist, and several words omitted. In the MS. the whole passage reads: '*von dort würde sie abermals nach der besten Bahn*[*un*]*g gehen, u dgl* [*und dergleichen*]. *Diese Tendenz nach der besten Bahn*[*un*]*g zu gehen wird aber gestört werden* . . .']

(their [amount of] facilitation being in that order), and that *d* lies in the neighbourhood of the wishful cathexis +*V*, then the consequence may be that the $Q\phi$, in spite of the facilitations, will flow not to *c* and *b* but to *d*, and from there to +*V*; and thus the pathway *W*–*a*–*d*– +*V* will be revealed as the one that is being sought. Here there is in operation the principle which we have long recognized [p. 344 above] that cathexis can divert facilitation and can thus operate against it, and that accordingly a side cathexis modifies the passage of $Q\eta$. Since cathexes can be changed, it lies within the choice of the ego to modify the passage [of association] from *W* in the direction of any purposive cathexis.

What is to be understood here by a purposive cathexis is not a uniform one, such as affects a whole region in the case of attention, but one that emphasizes, that stands out above the level of the ego. It must probably be assumed that, in this kind of thought with purposive cathexes, $Q\eta$ travels simultaneously from +*V* as well, so that the passage [of association] from *W* can be influenced not only from +*V* but also from its further halting points. In this situation, however, the pathway from +*V* . . . is known and fixed, but the pathway from *W* . . . *a* . . . has to be discovered. Since in fact our ego always entertains purposive cathexes – often a number of them at the same time – we can now understand both the difficulty of purely cognitive thought and also the possibility, in the case of practical thought, of the most various pathways being reached at various times under various conditions by various individuals.

In the case of practical thought, too, we arrive at an appreciation of the *difficulties in thinking* which, to be sure, we know from our own feeling. Let us return to our former example, in which the current of $Q\phi$ would flow, in accordance with the facilitation, to *b* and *c*,[1] while *d* is marked by a close link with the purposive cathexis or a consequential idea. Then the influence of the facilitation in favour of *b* . . . *c* may be so great as to outweigh by far the attraction of *d* . . . +*V*. In order nonetheless to direct the passage [of association] to +*V*, it would be necessary for the cathexis of +*V* and its derivative ideas to be still further increased, perhaps, too, for the attention to *W* [the perception] to be altered, so that a greater or lesser degree of binding might be attained and a level of current more favourable to the pathway *d* . . . +*V*. An expenditure of this kind for overcoming good facilitations, in order to entice the *Q* along pathways which are worse facilitated but lie closer to the purposive cathexis, corresponds to difficulty in thinking. [378]

1 [In the MS.: '*der Bahn*[*un*]*g nach nach b u*[*nd*] *c*.' One of these '*nachs*' is omitted in *Anf*., 456, spoiling the sense. Earlier in this sentence, '$Q\phi$' is misprinted '$G\phi$'.]

The part played by indications of quality in practical thought is little different from that played by them in cognitive thought. The indications of quality ensure and fix the passage [of association] but are not absolutely indispensable for it. If we put complexes instead of the neurons and complexes instead of the ideas,[1] we come up against a complication of practical thought which it is no longer possible to describe, and we realize that it becomes desirable here to [be able to] clear things up quickly. [Cf. p. 407 below.] During such [a passage of association], however, the indications of quality are for the most part not completely aroused, and, indeed, generating them serves to retard and to complicate the passage [of association]. When the passage from a particular perception to certain particular purposive cathexes has already been followed repeatedly, and has been stereotyped by mnemic facilitations, there will as a rule be no occasion to arouse indications of quality.

The aim of practical thought is *identity* [p. 354 f.], the debouching of the displaced $Q\phi$ cathexis into the wishful cathexis which has meanwhile been firmly retained. We must regard from a purely biological angle the fact that the need for thought thereupon ceases and that, instead, a full innervation is permitted of the *motor images* touched upon on the path, which represent what is in the circumstances a justified accessory part of the *specific action* [p. 321]. Since during the passage [of association] this motor image was only cathected in a bound manner, and since the thought process started from a perceptual image which was then followed only as a mnemic image, the whole thought process is able to make itself independent of the expectational process and of reality and is able to advance in a quite unaltered manner as far as identity. Thus it starts from a mere *idea*, and, even after it is completed, does not lead to action; but it has produced a piece of *practical knowledge*, which can be used for a subsequent real occurrence. For in fact it proves expedient not to have to set the process of practical thought going only when it is needed in the face of reality, but to have it ready in advance.

The time has now come to qualify a hypothesis made earlier [pp. 389–90], to the effect, namely, that a memory of thought processes is made possible only by indications of quality, because otherwise their traces could not be distinguished from the traces of perceptual facilitations. It
[379] still holds good of this that a *real memory* should properly not be modified by any amount of thought about it. On the other hand, it is undeniable that thought about a topic leaves extraordinarily important traces behind for any subsequent rethinking about it [cf. pp. 324 and 360]; and it is very

1 [Cf. p. 353 above. *Anf.*, 456, inserts '*einzelnen*' ('single') in front of 'neurons' and 'ideas'.]

questionable whether this is brought about only by thought accompanied by indications of quality and consciousness. There must therefore be thought facilitations, and yet the original paths of association must not be obliterated. Since there can only be one kind of facilitation, it might be thought that these two conclusions are incompatible. Yet it must be possible to find a means of reconciling and explaining them in the fact that thought facilitations were all first created at a high level [of cathexis] and that they probably also come into effect at a high level once more, whereas associative facilitations, which originated during full or primary passages [of quantity], reappear when conditions for an unbound[1] passage [of quantity] are established. Accordingly, then, some possible effect by thought facilitations upon associative facilitations is not to be denied.

Thus we arrive at the following further characterization of the unknown neuronal motion:

Memory consists in the facilitations [p. 324 above]. Facilitations are not altered by a rise in the level [of cathexis]; but there are facilitations that come into effect only at a particular level. The direction of the passage [of quantity] is not altered in the first place by an alteration of level, though no doubt it is by the quantity of current [p. 399] and by side cathexes [p. 400]. Where the level is high, it is preferably small *Q*s that are displaceable [p. 391].

Alongside of *cognitive* and practical thought, we must distinguish a reproductive, *remembering* thought, which in part enters into practical thought, but does not exhaust it.

This *remembering* is a precondition of all testing by critical thought: it follows back a given thought process in a reversed direction, as far back, perhaps, as a perception – once again, in contrast to practical thought, without an aim – and, in doing so, makes use to a large extent of indications of quality. In thus following a backward direction, the process comes upon intermediate links which have hitherto been unconscious, which have left no indications of quality behind them but whose indications of quality appear subsequently [*nachträglich*]. This implies that the [380]
passage of thought in itself, without any indications of quality, has left traces behind it. In some instances, indeed, it looks here as though we should only be able to guess certain stretches of the pathway because their starting and end points are given by indications of quality.

1 [In the MS.: '*wenn die Beding*[*un*]*gen des ungeb. Ablaufes hergestellt sind*.' The '*ungeb*.' presumably stands for '*ungebunden*'. *Anf*., 457, having evidently read the MS. as '*umgeb*', expands it into '*umgebenden*' ('surrounding').]

In any case, the reproducibility of thought processes goes far beyond their indications of quality; they can be made conscious subsequently [*nachträglich*], though perhaps the *outcome*[1] of a passage of thought leaves traces behind it more often than its intermediate stages.[2]

During a passage of thought, whether it is *cognitive*, *testing* or *practical* thought, all kinds of events may occur which deserve to be described. Thought may lead to *unpleasure* or to *contradiction*. Let us follow the case in which practical thought with purposive cathexes leads to a release of unpleasure. [Cf. p. 381 ff. above.]

The most ordinary experience shows that this event results in an obstacle to the thought process. How is it that it can come about at all? If a memory, when it is cathected, generates unpleasure, that is in general due to the fact that the corresponding perception had generated unpleasure when it occurred – that is, was part of an experience of pain [p. 345 ff.]. Perceptions of this kind, as we know from experience, attract a high degree of attention to themselves, but they arouse fewer indications of quality of their own than of the reaction which they [the perceptions] occasion: they are associated with their own manifestations of affect and defence [pp. 346–7]. If we follow the vicissitudes [*Schicksal*][T] of perceptions like these when [they have become] *mnemic* images, we notice that their first repetitions continue to arouse affect and also unpleasure, till in time they lose this capacity. Simultaneously, another change takes place in them. To begin with, they have retained the characteristic of sensory qualities; when they are no longer capable of affect, they lose these [sensory qualities] too and come to resemble other mnemic images. If a passage of thought comes up against a still *untamed mnemic* image of this kind, then its indications of quality, often of a sensory kind, are generated, with a feeling of unpleasure and an inclination to discharge, the combination of which characterizes a particular affect, and the passage of thought is interrupted.

[381] What is it, then, that happens to *memories* capable of affect till they are *tamed*? It cannot be supposed that 'time', repetition, weakens their capacity for affect, since ordinarily that factor [repetition] actually contributes to strengthening an association.[3] Something must no doubt

1 [Translator's italics.]

2 [Here, as on p. 396 above, there is a transverse line in the MS., unmarked in *Anf.*, 458, which seems to indicate a new section.]

3 [In the MS., the middle part of this sentence reads: '. . . *dass die "Zeit", die Wiederhol*[*un*]*g ihre Affektfähigkeit abschwächt* . . .' *Anf.*, 459, prints this: '. . . *dass die "Zeit" die Wiederholung ihrer Affektfähigkeit abschwächt* . . .' By thus dropping the comma after '"*Zeit*"' and changing '*ihre*'

happen in [the course of] 'time', during the repetitions, which brings about this subjugation [of the memories]; and this can be nothing other than that a relation to the ego or to ego cathexes obtains power over the memories. If that takes longer in this case than it does usually, a special reason for it can be found – namely, in the origin of these memories with their capacity for affect. Being traces of experiences of pain, they have been cathected (according to our hypothesis about pain [pp. 331–2 above]) with excessively large $Q\phi$ and have acquired an excessively strong facilitation to the release of unpleasure and affect.[1] Particularly large and repeated binding from the ego is required before this facilitation to unpleasure can be counterbalanced.

The fact that a memory exhibits a hallucinatory characteristic for so long also calls for an explanation – important for our view of hallucination. Here it is plausible to suppose that this capacity for hallucination, as well as the capacity for affect, are indications of the fact that the ego cathexis has not yet gained any influence on the memory, that the primary lines of discharge and the full or primary process predominate in it.

We are obliged to see in [the state of] being hallucinated a backward flow of Q to ϕ and also to ω[2] [p. 364 f. above]; thus a bound neuron does not admit of such a backward flow. It may also be asked whether it is the excessively large quantity of cathexis of the memory which makes the backward flow possible. Here, however, we must recall that a large Q of this kind is only present the first time, at the actual experience of pain. On repetition, we are only[3] dealing with a cathexis of ordinary strength, which nevertheless brings about hallucination and unpleasure – thanks, [382]
we can only suppose, to an unusually strong facilitation. It follows from this that an ordinary ϕ quantity[4] is no doubt sufficient to produce backward flow and an excitation towards discharge, and the inhibiting effect of binding by the ego gains in significance.

In the end, then, it becomes possible to cathect the memory of the pain in such a way that it cannot exhibit any backward flow and can release only minimal unpleasure. It is now tamed, and by a thought facilitation strong enough to exercise a permanent effect and to produce an

into '*ihrer*', it gives the meaning: 'It cannot be supposed that "time" weakens the repetition of their capacity for affect.' This seems to make very little sense, especially in view of what follows. The solution offered above (and in *GW*, **Nachtr.**, 470) – that 'repetition' is in apposition to '"time"' and intended to explain it – seems more probable.]

1 ['*Unlust- u Affektentbind*[*un*]*g*' in the MS. *Anf.*, 459, reads: '*Unlust- und Affektbindung*' ('binding of unpleasure and affect').]

2 [Cf., however, Freud's later correction of this, p. 414 below.]

3 ['*nur*' in the MS. Omitted in *Anf.*, 460.]

4 [Equivalent to the abbreviation '$Q\phi$'. See p. 396 above.]

inhibiting action once more at every later repetition of the memory. The pathway leading to the release of unpleasure will then, owing to disuse, gradually increase its resistance: for facilitations are subject to gradual decay (forgetting). Only after this is [the] memory a tamed memory like any other.[1]

It nevertheless appears that this process of subjugating the memory leaves a permanent effect on the passage of thought. Since earlier the passage of thought was disturbed every time the memory was activated and unpleasure aroused, there is a trend even now towards inhibiting the passage of thought as soon as the tamed memory generates its trace[2] of unpleasure. This trend is most serviceable for practical thought, since an intermediate link that leads to unpleasure cannot lie on the sought-for pathway to identity with the wishful cathexis [p. 355 above]. Thus primary *thought defence* arises, which, in practical thought, takes the release of unpleasure as a signal [p. 351 f.] to leave a particular pathway – that is, to direct the cathexis of attention *elsewhere*. Here, once again, unpleasure directs the current of $Q\eta$, as in the first biological rule [p. 394]. It must be asked why this thought defence was not directed against the memory while it was still capable of affect. But at that point, we may
[383] suppose, an objection was raised by the second biological rule, which calls for attention where an indication of reality is present [p. 395], and the untamed memory was still able to enforce real indications of quality. The two rules, as we see, are in harmony in serving a useful purpose.

It is interesting to see how practical thought lets itself be guided by the biological rule of *defence*. In theoretical (cognitive and testing) [thought][3] the rule is no longer observed. This is intelligible, for with purposive thought it is a question of *some* pathway *or other* and, accordingly, those to which unpleasure attaches can be excluded; whereas with theoretical [thought] every pathway must be cognized.

1 [It is interesting to note that more than forty years later Freud used the same term '*Bändigung*' ('taming') in a rather similar connection. This was in Section III of his paper 'Analysis Terminable and Interminable' (1937*c*), *RSE*, **23**, 203, where he discusses the possibility of 'taming' a drive by the strength of the ego. He had, some time earlier, in 'The Economic Problem of Masochism' (1924*c*), ibid., **19**, 155, used the term of the 'taming' of the death drive by fusion with the libido. (The term also appears in Letter 69 to Fliess of September 21, 1897, p. 286 above.) – The question of the normal fading of memories is discussed in a long footnote added in 1907 to *The Psychopathology of Everyday Life* (1901*b*), *RSE*, **6**, 235–6 *n*. 3. Freud had touched on the problem even before the date of the present work, in his lecture on 'The Mechanism of Hysterical Phenomena' (1893*h*), ibid., **3**, 36.]

2 ['*Spur*.' The meaning, however, is identical to 'signal' (cf. Freud, 1926*d*; ibid., **20**).]

3 ['*Denken*' supplied in *Anf*., 461; not in the MS.]

[4]

The further question now arises of how *error* can occur in the course of thought. What is error?

The process of thought must now be considered still more closely. Practical thought, the origin of all thought processes, remains, too, their final aim. All other kinds branched off from it. It is an obvious advantage if the arranging of thought,[1] which takes place in practical thought, need not wait to occur till the state of expectation but can have occurred already [p. 402 above]: because (1) this will save time for the specific action to take shape [p. 402], (2) the state of expectation is far from being particularly favourable for the passage of thought. The value of promptitude in the short interval between perception and action is shown when we consider that perceptions change rapidly. If the thought process lasts too long, its product will have become useless in the meantime. For that reason we '*think ahead*'.

The beginning of the thought processes which have ramified [from practical thought] is the forming of judgements.[2] The ego arrived at this through a discovery in its organization – through the fact already mentioned [pp. 356 f. and 389] that perceptual cathexes coincide in part with information from one's own body. As a consequence, the perceptual complexes are divided into a constant, non-understood, part – the *thing* – and a changing, understandable, one – the attribute or movement of the thing. Since the thing complex recurs linked with a number of attribute complexes, and these recur linked with a number of thing complexes, a possibility arises of working out the pathways of thought leading from [384]
these two kinds of complex to the wished-for state of the thing, [and of doing so] in a manner which is, as it were, valid generally and without regard to the perception which is the real one at the moment. Thus activity of thought with judgements, instead of with separate perceptual complexes that have not been set in order, is a great saving. We must leave on one side the question of whether the psychological unity thus achieved is represented in the passage of thought by a neuronal unity, too, and by a unity other than the word presentation.

Error can already make its way in during the creating of a judgement. For the thing complex and movement complex are never quite identical, and among their divergent components there may be some the neglect of which disturbs the outcome in reality. This defect in thought originates

1 ['*Denküberführung*', literally 'transportation of thought'.]

2 [For what follows, cf. Sections 16 and 17 of Part I.]

from the endeavour, which, indeed, we are copying here, to substitute a single neuron for the complex – which is necessitated precisely by the immense complexity. [Cf. p. 402 above.] *These are mistakes in judgement or faults in the premises*.

Another ground for error may lie in the fact that the perceptions[1] of reality have not been completely perceived because they were not within range of the senses. These are *errors of ignorance*, which no human being can avoid. Where this determinant does not apply, the psychical precathexis may be defective (owing to the ego being deflected away from the perceptions) and inaccurate perceptions and incomplete passages of thought may result. These are *errors* due to *insufficient attention*.

If now we take as the material of the thought processes complexes that have been judged and set in order, instead of unsophisticated ones, an opportunity arises for shortening the practical thought process itself. For if it has turned out that the pathway from perception to identity with the wishful cathexis leads by way of a motor image *M*, then it is biologically ensured that after identity has been achieved this *M* will be fully innervated. Owing to the simultaneity of the perception and this *M*, an intense facilitation develops between the two of them, and an immediately subsequent perceptual image[2] will arouse the *M* without any further passage of association. In saying this, we are of course assuming that it is possible at any time to establish a link between two cathexes. What was originally
[385] a laboriously established thought connection afterwards becomes, owing to simultaneous full cathexis, a powerful facilitation. The only question about it is whether it is always[3] effected along the pathway that was first discovered or whether a more direct connection may be followed. The latter seems more likely and more expedient, since it spares the necessity for fixing pathways of thought which should, indeed, remain free for other connections of the most various kinds. If the [original] pathway of thought is not followed again, no facilitation of it is to be expected either, and the outcome will be better fixed by a more direct connection. It remains an open question, incidentally, whence the new pathway would originate. If the two cathexes, the perception and *M*, had a common association with a third one, the problem would be simplified.

1 ['*W*' in the MS. This is expanded by *Anf*., 462, into '*Wahrnehmungsobjekte*' ('objects of perception').]

2 ['*Ein nächstes W*' in the MS. The '*W*' must therefore stand for the neuter word '*Wahrnehmungsbild*'. *Anf*., 463, alters this to the feminine '*eine nächste Wahrnehmung*' ('perception').]

3 ['*stets*.' MS. is unclear; it could be '*statt*' ('instead') which makes less sense.]

The portion of passage of thought from the perception to identity by way of an M[1] can also be emphasized and will lead to a similar outcome if afterwards attention fixes the *M* and brings it into association with the perception, which has also been once more fixed. This thought facilitation, too, will be set up again when there is a real occurrence.

It is not at once plain how errors can occur in this [kind of] thought activity. But no doubt an inexpedient pathway of thought may be entered upon and a wasteful movement emphasized, since with practical thought the choice is after all dependent only on reproducible experiences.

With increasing memories fresh pathways of displacement are constantly appearing. For that reason it is found advantageous to follow the different perceptions completely in order among all the pathways to discover the most favourable; and this is the work of *cognitive* thought, which, to be sure,[2] emerges as a preparation for practical [thought], though in fact it only developed out of the latter at a late stage. The results of this [work][3] are thereafter serviceable for more than one kind of wishful cathexis.

The errors of cognitive thought are self-evident. They are partiality, where purposive cathexes have not been avoided, and incompleteness, [386]
where every pathway has not been followed. Clearly it is an enormous advantage here if indications of quality have been aroused simultaneously. If these thought processes [the indications of quality] are picked out and introduced into the state of expectation, the passage of association from its first to its last link can go by way of the indications of quality instead of going through the entire series of thoughts,[4] and here it is not even necessary for the series of qualities to correspond completely to the series of thoughts.

In theoretical thought unpleasure plays no part, and it is therefore possible as well with tamed memories.

We have still to consider one kind of thought: critical or examining thought. This is occasioned when, in spite of all the rules having been observed, the process of expectation, followed by the specific action, leads to unpleasure instead of to satisfaction. Critical thought seeks,

1 [Here and in the next line *Anf*., 463, has '*Bewegungsbild*' ('motor image'), instead of '*M*' as in the previous two paragraphs.]

2 [A word in the MS. here is hard to make out. *Anf*., 464, prints it as '*so*' ('thus'), which it almost certainly is not. A probable solution is '*zw*' for '*zwar*' ('to be sure').]

3 [The MS. has plainly '*derselben*' (feminine) for 'this' – which can only refer back to '*Arbeit*' ('work'). *Anf*., 464, changes the word to '*desselben*' (masculine or neuter) and so makes the 'this' refer perhaps to 'cognitive thought'. Curiously, *GW*, **Nachtr**., 475, retains '*desselben*'.]

4 ['*Denkreihe*' in the MS. (as just below); here, though not below, *Anf*., 464, has '*Denkweite*' ('extent of thought').]

without a practical aim, in a leisurely manner, and summoning up all the indications of quality, to repeat the whole passage of *Qη*[1] in order to detect some *fault in thought* or some *psychological defect*. It [critical thought] is cognitive thought with a given object – namely, a series of thoughts. We have heard what these latter [? psychological defects] consist in; but in what do *logical faults* consist?

Stated briefly, in the non-observance of the *biological rules* for the passage of thought. These rules lay down where it is that the cathexis of attention is to be directed each time and when the thought process is to come to a stop. They are protected by threats of unpleasure, they are derived from experience, and they can be transposed directly into the rules of logic – which will have to be proved in detail. Thus the intellectual unpleasure of contradiction, at which the passage of testing thought comes to a stop, is nothing other than the [unpleasure] accumulated for the protection of the biological rules, which is stirred up by an incorrect thought process.

The existence of biological rules of this kind can in fact be proved from the feeling of unpleasure at logical faults.

Action, again, we cannot, however, picture other than as the full cathexis of those motor images which have been brought into prominence during the thought process [p. 408 f. above], in addition, perhaps, to those which (if there was a state of expectation) formed part of the volitional component of the specific action[t]. Here the bound state is
[387] renounced and the cathexes of attention are withdrawn. What no doubt happens as regards the former [the renunciation of the bound state] is that at the first passage [of *Q*] from the motor neurons the level in the ego falls irresistibly. A total unloading of the ego is of course not to be expected in the case of single actions, but only in the case of acts of satisfaction of the most ample kind. It is an instructive fact that action does not occur by an inversion of the path which brought the [kinaesthetic] motor images but along special motor pathways; and for that reason the outcome of the movement[2] is not as a matter of course also the one wished for, as it would necessarily be if the same path were inverted. During the action, therefore, a fresh comparison must be made between the information which arrives of movements and the precathected

1 ['*Qη ablauf*' in the MS. *Anf.*, 464, has '*Qualitätsablauf*' ('passage of quality').]

2 [*Anf.*, 465, reads: '*Bewegungsaffekt*' ('the affect attaching to the movement'). Merton Gill suggested to Strachey that this should read '*effekt*'. With either reading the implication is the same: satisfaction (i.e. unloading of *Q*) does not occur as a matter of course. The MS. offers no clear decision.]

[desired movements], and there must be an excitation of correcting innervations till identity is achieved. The same thing is repeated here which occurred on the perceptual side, though with less multiplicity, more rapidity and continuous *full* discharge, which was absent in the other instance [in that of perceptions]. The analogy, however, between practical thought and expedient action is noteworthy. We can see from it that motor images are *sensory*.[1] But the peculiar fact that with action fresh pathways are entered upon, instead of the so much simpler inversion, seems to show that the direction taken by the conduction of the neuronal elements is a firmly fixed one, and perhaps, indeed, that the neuronal motion may have different characteristics in the two cases.

Motor images are perceptions and, as such, of course have quality and arouse consciousness. Nor can it be disputed that they sometimes draw large attention to themselves. Their qualities, however, are not very striking, and probably not so multifarious as those of the external world; and they are not associated with word presentations, but, on the contrary, they themselves serve in part the purposes of that association. They do not arise, however, from highly organized sense organs; their quality is no doubt monotonous [pp. 335–6 above].

1 [The whole sense of this paragraph is opaque unless the distinction between afferent (kinaesthetic) motor 'images' and efferent motor *discharge* is appreciated. Cf. p. 388 above.]

APPENDIX B

EXTRACT FROM FREUD'S LETTER 39 TO FLIESS OF JANUARY 1, 1896[1]

. . . Your remarks on migraine[2] have led me to an idea which would result [388]
in a complete recasting of all my $\phi\psi\omega$ theories, on which I cannot venture now. But I will try to give a hint of it.

I start from the two kinds of nerve-endings. The free ones [p. 330 above] receive only quantity and conduct it to ψ by summation [p. 341]; they have no power, however, to evoke sensation – that is, to affect ω. In this connection the neuronal motion retains its genuine and monotonous qualitative characteristics [p. 335]. These are the paths for all the quantity that fills ψ, also, of course, the paths for sexual energy.[3] The nerve paths which start from end-organs do not conduct quantity but the qualitative characteristic peculiar to them; they add nothing to the amount in the ψ neurons, but merely put these neurons into a state of excitation.[4] The ω neurons are those ψ neurons which are capable of only very little quantitative cathexis. The coincidence between these minimal quantities and the quality faithfully transferred to them from the end-organ is once more the necessary condition for the generating of consciousness. I now [in my new scheme] insert these ω neurons between the ϕ neurons and the ψ neurons, so that ϕ transfers its quality to ω, and ω now transfers neither quality nor quantity to ψ but merely excites

1 [As explained in the note on p. 247 above, this letter has been transposed from its chronological position among Freud's other letters to Fliess. The earlier part of it contains a revision of the views expressed in the 'Project' and is only intelligible by reference to it. The later part of the letter attaches rather to Draft I, p. 241 above. It is concerned with migraine and is related to Fliess's theories of the importance of the nasal areas in neurotic and especially in sexual disorders. See also Freud's review (1895*j*) of Moebius's book on migraine and the editorial comment on it (*NSW*, **4**; *RSE*, **3**, 135 ff.).]

2 [Nothing is known of these.]

3 [In *Anf.*, 153, the second '*für*' ('for') has been displaced from this sentence to the beginning of the next sentence. – Regarding the monotonous character of endogenous stimulation, however, see the Editors' Introduction to the 'Project' (p. 313 *n.* 2 above).]

4 [The radical implication of this recasting of the model is that all Q is endogenous; the ϕ paths transmit only qualitative information which influences the existing Q processes in ψ. – This presumably explains the disappearance of the distinction between Q and $Q\eta$ in this revision. Here Freud speaks only of Q, the forerunner of 'psychical energy' (see Appendix C below).]

ψ – that is, indicates the pathways to be taken by the free ψ[1] energy. (I don't know whether you can understand this double Dutch. There are, so to say, three ways in which the neurons affect one another: (1) they
[389] transfer quantity to one another, (2) they transfer quality to one another, (3) they have an exciting effect on one another in accordance with certain rules.)

On this view the perceptual processes would *eo ipso*[2] [from their very nature] involve consciousness and would only produce their further psych[ical] effects *after* becoming conscious. The ψ processes would in themselves be unconscious and would only subsequently [*nachträglich*] acquire a secondary, artificial consciousness through being linked with processes of discharge and perception (speech association) [p. 389 above]. An ω discharge, which my other account necessitated [pp. 333–4], now becomes unnecessary; hallucination, whose explanation always raised difficulties, is now no longer a backward movement of excitation to ϕ[3] [p. 405] but only to ω. It is much easier today to understand the rule of defence, which does not apply to perceptions, but only to ψ processes. The fact that secondary consciousness [see above] lags behind makes it possible to give a simple description of the processes of neuroses.[4] I am also relieved of the troublesome question of how much of the strength of ϕ excitation (of sensory stimuli) is transferred to ψ neurons. The answer is: none at all, directly. The Q in ψ depends only on how far the free ψ attention is directed by the ω neurons.

The new hypothesis also fits in better with the fact that the objective sensory stimuli are so minimal that it is hard to derive the force of the will from that source in accordance with the principle of constancy. Sensation, however, [on the new theory] brings no Q at all to ψ; the source of ψ energy is the [endogenous] organic paths of conduction.

I also see the explanation of the release of unpleasure, which I need for repression in the sexual neuroses, in the conflict between the purely quantitative organic conduction and the processes *excited* in ψ by conscious sensation.

As regards *your* side of the question, the possibility arises that states of

1 [This is incorrectly expanded to '*psychischen*' in *Anf.*, 153. The meaning is not 'psychical energy' in the sense used in Freud's later works, but 'energy arising from the ψ system'. – The functional distinction between ϕ and ω largely collapses here, which anticipates Freud's later (1916–17*f* [1915]) merging of *Pcpt.* and *Cs.* into a single functional unit *Pcpt.-Cs.* (See p. 313 *n.* 2 above.)]

2 [Translator's italics.]

3 [*Anf.*, 153, has 'ψ'.]

4 [At this point in *Anf.*, 153, '(*sic!*)' has been inserted.]

stimulation may occur in organs which produce no spontaneous sensation (though they must no doubt exhibit susceptibility to pressure), but which can by reflex action (that is, through the influence of equilibrium) instigate disturbances arising from other nerve centres. For the thought of there being a reciprocal binding of the neurons or of the nerve centres also suggests that the motor symptoms of discharge are of various kinds. Voluntary actions are probably determined by a transference of Q, since they discharge psychical tension. In addition to this there is a discharge of pleasure, spasms, etc., which I explain, not by Q being [390] transferred to the motor centre, but by its being liberated there because the binding Q in the sensory centre coupled with it may have diminished [p. 363 above]. This would give us the long-sought-for distinction between 'voluntary and spastic' movements, and at the same time a means of explaining a group of subsidiary somatic effects – in hysteria, for instance.

In respect to the purely quantitative processes of transference to ψ, there is a possibility of their attracting consciousness to themselves – if, that is to say, such conductions of Q fulfil the conditions necessary for producing pain. Of those conditions the essential one is probably the suspension of summation and a continuous afflux [of Q] to ψ for a time. Certain ω neurons then become *hyper*cathected and produce a feeling of unpleasure, and they also cause attention to be riveted at that point. Thus 'neuralgic change' would have to be regarded as an afflux of Q from some organ augmented beyond a certain limit till summation is suspended, the ω neurons hypercathected and free ψ energy riveted. As you see, we have arrived at migraine; the necessary precondition would be the existence of nasal regions in the state of stimulation which you recognized by naked eye. The surplus of Q would be distributed along various subcortical paths before reaching ψ. When once this has happened, a continuous Q forces its way into ψ and, in accordance with the rule of attention [p. 395 above], the free ψ energy flows to the seat of the eruption.

The question now arises as to the source of the states of stimulation in the nasal organs. The idea suggests itself that the qualitative organ for olfactory stimuli may be Schneider's membrane and the quantitative organ (distinct from this) may be the *corpora cavernosa*.[1] Olfactory substances, as, indeed, you yourself believe, and as we learn from the

1 [Erectile tissue. The suggestion here is that Schneider's membrane is the ϕ end-organ for external olfactory stimulation of the ψ pallium, whereas the erectile tissue of the nose relays endogenous (sexual) Q to the ψ nucleus.]

flowers, are breakdown products of the sexual metabolism; they would act as stimuli upon both these organs. During menstruation and other sexual processes the body produces an increased *Q* of these substances and therefore of these stimuli. It would have to be decided whether these act on the nasal organs through the expiratory air or through the blood vessels; probably the latter, since one has no subjective sensation of smell before migraine. Thus the nose would, as it were, receive information about *internal* olfactory stimuli by means of the *corpora cavernosa*, just as it does about external stimuli by Schneider's membrane: one would come to grief from one's own body. The two ways of acquiring migraine – spontaneously and through smells, human toxic emanations [p. 242 above], would thus be equivalent and their effects could at any time be brought about by summation.

[391] Thus the swelling of the nasal organs of quantity would be a kind of adaptation of the sense organ resulting from increased internal stimulation, analogous in the case of the true (qualitative) sense organs to opening the eyes wide and focusing them, straining the ears, and so on.

It would not be too hard, perhaps, to transfer this conception to the other sources of migraine and similar conditions, though I cannot yet see how it is to be done. In any case it is more important to test the idea in relation to the main topic.

In this way a whole number of obscure and ancient medical ideas acquire life and value.

. . . . . .

APPENDIX C

THE NATURE OF *Q*

Of the two 'principal theorems' with which Freud introduces the 'Project' (p. 319 above) – the neuron and *Q* – there is no mystery about the first. But the second calls for some examination, especially as everything suggests that it was the forerunner of a concept that was to play a fundamental part in psychoanalysis. We are not concerned here with the special puzzle, mentioned above in the Editors' Introduction, of the distinction between *Q* and *Qη*. What we are dealing with is *Qη* (as Freud himself explicitly states at the end of his first paragraph) – a *Q* that has some special connection with the nervous system. [392]

How, then, did Freud picture this *Q* in the autumn of 1895?

Apart from the obvious fact that he wanted to present *Q* as something material – 'subject to the general laws of motion' (p. 319) – we notice at once that *Q* appears in two distinguishable forms. The first of these is *Q* in flow, passing from one neuron to another. This is described in various ways: for instance, 'neuronal excitation . . . in a state of flow' (p. 320), '*Q* in flow' (p. 325), 'current' (p. 322) or 'passage of excitation' (p. 323). The second, more static, form is *Q* entering a neuron without being transferred onwards, shown by 'a *cathected* neuron filled with' *Q* (p. 322).[1] The two forms of *Q* presumably coincide with the general notion of 'kinetic' versus 'potential' energy.

The importance of this distinction between the two states of *Q* only emerges by degrees in the 'Project', and one is almost tempted to imagine that Freud himself only became aware of it in the course of his writing the work. The first sign of this importance is in connection with the discussion of the mechanism for telling the difference between hallucinations and perceptions, and the part played in this mechanism by inhibitory action arising from the ego (Sections 14 and 15 of Part I). The details of this inhibitory action (interference by a 'side cathexis', directed by a cathexis of attention from the ego) are given on pp. 347–9, and its outcome is to change the state of *Q* which is in flow into a state of *Q* which is static in a neuron. This distinction is presently (pp. 351–3) related to one between the primary (uninhibited) and secondary (inhibited) processes. Yet another way of describing the same distinction is introduced soon afterwards (p. 360) with the notion that the interfering side cathexis has a 'binding' effect on the *Q*.[2] It is not, however, until in Part III of the 'Project' (p. 392 f.) that the full implications are displayed of the distinction between a bound and a mobile [393]

1 Cf. some remarks on cathexis in the Editors' Appendix to Freud's first paper on the neuropsychoses of defence (1894*a*), *RSE*, **3**, 59.

2 Freud's use of the term 'binding' presumably refers to Helmholtz's distinction between 'bound' and 'free' energy.

state of *Q*. The necessity for the hypothesis of there being two states of *Q* arises at that point in connection with Freud's discussion of the mechanism of thinking, which calls for a state in the neuron 'which, though there is a high cathexis, permits only a small current' (p. 392 above).

Thus *Q* would appear to be measurable in two ways: by the height of the level of cathexis within a neuron and by the amount of flow between cathexes. This has been seized upon sometimes as evidence that Freud really believed that *Q* was simply electricity and that the two ways of measuring it corresponded to amperage and voltage (see Editors' footnote 1, p. 325 above). Indeed, some eighteen months before the composition of the 'Project', in his first paper on the neuropsychoses of defence (1894*a*), he had made a comparison between something that was a precursor to *Q* and 'an electric charge . . . spread over the surface of a body' (*RSE*, **3**, 56). Breuer, too, in his theoretical contribution to *Studies on Hysteria* (1895*d*), published only a few months before the 'Project' was written, devoted some space to an electrical analogy to the 'excitations' in the 'conductive paths of the brain' (ibid., **2**, 173). The electrical nature of neuronal transmission was in fact well understood by 1895 (see Shepherd, 1991). Nevertheless, nowhere in the 'Project' is the physiology of *Q* explicitly described. On the contrary, Freud repeatedly emphasizes the fact that the nature of 'neuronal motion' is unknown to us. (See, for instance, pp. 396, 403 and 410 f. above.)[1]

There are, it must be admitted, some obscurities in the account given in the 'Project' of the nature of the 'bound' state and of its mechanism. One of the most puzzling of these relates to the account given of the process of 'judgement' and the part played in it by a cathexis from the ego. This influence is described in a variety of ways – as a 'side cathexis', or 'precathexis', or 'hypercathexis'[2] – and it is closely involved in the idea of a cathexis of attention. It seems at first (e.g. p. 349) that attention
[394] is only a means of directing the side cathexes to the place where they are needed. But elsewhere (e.g. p. 392) it seems as though the hypercathexis of attention is in itself the force which produces the 'bound' state.

Indeed, the whole question of the relation of attention to *Q* needs examination. Attention makes an unostentatious appearance in Section 14 of Part I (p. 349), but soon begins to show its importance (in Section 19 of Part I and Section 6 of Part II), while in Part III it becomes an almost predominant feature. Nevertheless, in Freud's later writings, 'attention' almost vanishes, apart from a few sporadic mentions. Anonymous traces of it, however, persist to the very last along two rather different

1 Pribram & Gill (1976) are of the opinion that this is no doubt due to the fact that, although the electrical nature of the nerve impulse was obvious by 1895, the physiological events (within the neuron) that brought it about were not well understood. Thus it was clear to Freud that an electrical charge accumulated in the neuron (cathexis) and was propagated by it (*Q* in flow), but the physiological events within the cell by means of which this occurred (neuronal motion) were unknown to him. The neurochemical nature of 'neuronal motion' could accordingly not be described, only its manifestation in electrical activity. Nevertheless, as we have seen, Freud intuited that neuronal motion had something to do with the permeability of the cell membrane (contact barrier) which became the physiological basis of the third principal idea in the 'Project' – facilitation. Facilitation then became the basis of all representation in the mental apparatus, while *Q* became the basis of the 'quotas of affect' – psychical energy – by means of which representations are cathected.

2 Incidentally, there seems to be little justification for the idea that Freud restricted his use of this last term to cathexes from the ego. See, for instance, 'libidinal hypercathexis' in *Totem and Taboo* (1912–13*a*), *RSE*, **13**, 87.

lines, both of which go back ultimately to the 'Project'. The first and more obvious one relates to the perceptual scanning of reality and to 'reality-testing'; and the history of this is fully documented in the Editors' Note to the metapsychological discussion of dreams (1916–17*f* [1915]), *RSE*, **14**, 195–6. The other, less noticeable but perhaps more important, concerns precisely the part played by attention or some similar agency in bringing about the distinction between *Q* in its bound and in its free state, and, beyond that, between the primary and secondary processes. This function of attention is discussed in an Editors' footnote to 'The Unconscious' (1915*e*), ibid., **14**, 169 f. *n*. 3. It is indirectly alluded to in Freud's very last works, *Moses and Monotheism* (1939*a*), ibid., **23**, 89, and the *Outline of Psychoanalysis* (1940*a* [1938]), ibid., **23**, 148.[1]

Whatever may be the precise details of the mechanism responsible for bringing about the transformation of free into bound *Q*, it is evident that Freud attached the greatest importance to the distinction itself. 'In my opinion,' he wrote in 'The Unconscious', 'this distinction represents the deepest insight we have gained up to the present into the nature of nervous energy' (ibid., **14**, 166).[2]

This quotation might also encourage us to hope that Freud's later writings will throw light on our immediate problem of the nature of *Q*. *Q* itself, under that name, never reappears, though there is no difficulty in recognizing it under various aliases, [395]
most of which are already familiar in the 'Project'. The most general one of these, 'psychical energy', demands attention, for it emphasizes what appears to be a vital change which the concept has undergone. *Q* is no longer 'something material'; it has become something psychical. 'Psychical energy' is found nowhere in the 'Project'.[3] ('ψ energy', which occurs in Letter 39, p. 415 above, etc., merely means 'energy from or in the neuronal system ψ'.) But it is already in common use in *The Interpretation of Dreams*. Nevertheless, the change does not portend a complete abandonment of a physical basis. Even though Freud declares (*RSE*, **5**, 478–9) that he 'shall remain upon psychological ground', careful examination will reveal traces of the old neurological background. Even the well-known passage in the book on *Jokes* (1905*c*; ibid., **8**, 129), in which he appears to turn his back on neurons, in fact leaves the door wide open for a physiological explanation. Indeed, in the sentence from the paper on 'The Unconscious' (1915*e*) quoted above, Freud speaks of 'nervous energy' not of 'psychical energy'. On the other hand, in the German collected edition of 1925 he altered two words in the last sentence of *Studies on Hysteria* (1895*d*) from 'nervous system' to 'mental life' (ibid., **2**, 272).

It would be a mistake to assume on this basis that 'psychical energy' can simply be reduced to what is known today about neuronal potentials. The principal reasons for this are, firstly, that in writing the 'Project' Freud aimed to 'represent psychical processes as quantitatively determinate states of specifiable material particles' and not the other way round. In other words, the fundamental mechanisms of the mind that

1 An interesting sidelight on Freud's view of attention is provided by his remarking, in several connections, that attention interferes with the efficiency of automatic actions, and that these are assisted by its distraction. See p. 29 above. Cf. also Freud (1901*b*), *RSE*, **6**, 28; (1905*c*), ibid., **8**, 131–3; and (1916–17*a*), ibid., **15**, 26 f.

2 Freud's strange and unexplained attribution of this discovery to Breuer is discussed in ibid., **2**, xxv f.

3 The term 'energy' occurs very rarely indeed in the 'Project' in the sense of '*Q*'. The commonest synonym used is probably 'excitation'.

he conceptualized here for the first time in neuronal terms were derived from clinical observation. They were psychical processes from the first, here temporarily translated and re-imagined in neuronal terms. Indeed, Freud states quite clearly on the first page of the 'Project' that his First Principal Theorem – *Q* – 'is derived directly from pathological clinical observation especially where excessively intense ideas were concerned'. The second and not unrelated reason becomes increasingly apparent as the 'Project' unfolds: the psychical processes that Freud conceptualized here were processes that required systems-level or *functional* descriptions. There is accordingly a significant hiatus between the principal theorems as applied at the outset to individual neurons and the nature of the psychical processes themselves described later. These entail vast assemblages of neurons, the behaviour of which necessarily entails the emergence of quite different governing theorems. Here too, in fact, Freud seems to have started with some vague intuitions at the functional level, derived from his clinical work, which he tried in this project to *reduce* to what was then known about cellular events. But, however great or small the revolution was by which 'nervous energy' was converted to 'psychical energy' in Freud's writings, there can be no question that many major characteristics of *Q* as described in this work survived in a transmogrified shape to the very end: evidence for this is given by the very numerous footnote references in these pages.

A particularly interesting question arises as to the relation of *Q* to the drives. These are scarcely mentioned here by that name. It is evident, however, that they are the successors to 'endogenous *Q*' or 'endogenous excitations'. Some history of Freud's developing views on the drives is given in the Editors' Note to 'Drives and their Vicissitudes' (1915*c*), *RSE*, **14**, 99 ff., and especially of his various classifications of them, first into libidinal and ego drives and later into libidinal and destructive drives. One point, not mentioned there, which is of special interest in the present context, is the suggestion, twice thrown out by Freud, of the possibility of an 'indifferent psychical energy' which may take either of the two drive forms: cf. the paper on narcissism (1914*c*), ibid., **14**, 67 f., and *The Ego and the Id* (1923*b*), ibid., **19**, 39. This 'indifferent psychical energy' seems very much like a harking back to *Q*.

[396] These later uncertainties about the drives (entities which, like *Q*, are 'on the frontier between the mental and the physical') and about their classification, remind us that Freud was always quite consistent in emphasizing our ignorance of the basic nature of *Q* or its doublets. This, as we have seen (p. 418 above), is often insisted on in the 'Project' itself. But the point recurs again and again in later works: to name only a few, in *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 536, in the paper on 'The Unconscious' (1915*e*), ibid., **14**, 166, and in *Moses and Monotheism* (1939*a*), ibid., **23**, 89. This conclusion is stated most plainly of all in *Beyond the Pleasure Principle* (1920*g*), ibid., **18**, 30: 'The indefiniteness of all our discussions on what we describe as metapsychology is of course due to the fact that we know nothing of the nature of the excitatory process that takes place in the elements of the psychical systems, and that we do not feel justified in framing any hypothesis on the subject. We are consequently operating all the time with a large unknown factor, which we are obliged to carry over into every new formula.' It seems, then, that our enquiry must end here and that we have no choice but to accept that Freud left the problem of *Q* unsolved.

But though the ultimate nature of *Q* was unknown to Freud, some of its essential features were always assumed by him and insisted upon to the end of his life. If we turn back to one of its very earliest appearances, to which we have already referred on p. 418 above, in the first paper on the neuropsychoses of defence (1894*a*), *RSE*, **3**, 56, we find this unknown entity described as something 'which possesses all the characteristics of a quantity (though we have no means of measuring it), which is capable of increase, diminution, displacement and discharge'. It is, indeed, obvious that the mysterious *Q* was given its name for the very reason that it did possess these characteristics.

Quantitative considerations had to be taken into account from the first at many points in Freud's theories. For instance, in 'The Aetiology of Hysteria' (1896*c*) we read that 'in the aetiology of the neuroses quantitative preconditions are as important as qualitative ones: there are threshold values which have to be crossed before the illness can become manifest' (ibid., **3**, 216). More important, however, is the fact that quantity is implicit in the whole theory of conflict as the cause not only of neuroses but also of an entire range of mental states. There are a number of passages in [397]
which this fact becomes explicit: for instance, in 'Types of Onset of Neurosis' (1912*c*), ibid., **12**, 231–2, in Lecture XXIII of the *Introductory Lectures* (1916–17*a*), ibid., **16**, 330, in 'Some Neurotic Mechanisms' (1922*b*), ibid., **18**, 220, and in 'Analysis Terminable and Interminable' (1937*c*), ibid., **23**, 204–5. In this last case the importance of quantitative factors is related to the therapeutic situation; and in the *New Introductory Lectures* (1933*a*), ibid., **22**, 136, Freud goes so far as to look forward to the day when our knowledge of neuroendocrine processes 'may give us the means of successfully combating the quantitative factors' in mental illness. But the same importance had been recognized more than forty years earlier, in Freud's contribution to *Studies on Hysteria* (1895*d*), ibid., **2**, 240. In his great paper on 'The Unconscious' (1915*e*) Freud used the term 'economic' as equivalent to 'quantitative', ibid., **14**, 160 f., and from that time onwards he used the words as synonyms.[1] We shall be right therefore in regarding our enigmatic *Q*, whatever its ultimate nature, as the progenitor of one of the three fundamental factors in metapsychology.

1 This identification was no novelty. It is to be found in a letter to Fliess (quoted above, p. 309) written several months before the 'Project'.

BIBLIOGRAPHY

Title page of the first edition of *Studies on Hysteria*

Title page of the first edition of Studies on Hysteria

It was published in May, 1895. Thirty years later, in his *Autobiographical Study*, Freud remembered the book like this: 'It did not seek to establish the nature of hysteria but merely to throw light upon the origin of its symptoms. Thus it laid stress upon the significance of the life of the emotions and upon the importance of distinguishing between mental acts which are unconscious and those which are conscious . . .' (*RSE*, **20**, 18).

NOTE ON THE REVISED TRANSLATION

The translations in this *Revised Standard Edition* are supplemented by four sets of notes:

(1) Lengthy commentaries on the English renditions of technical terms that are considered controversial are provided in Volume 24. Usually at the first appearance of each such technical term in each text, but sometimes in other places where the issue seems relevant, the original German word is interpolated in square brackets and a superscript upper-case [T] indicates that the term is discussed in the 24th volume. There (on pp. 55–99) the commentaries appear, in alphabetical order, under the heading 'Notes on the Translation of Some Technical Terms'. If the technical term appears in a derivate form in the text, the root word (as it appears in Volume 24) is provided in the margin. For example, if the interpolated word is the derivative [*überträgt*], the root technical term *Übertragung* appears in the margin.

(2) Shorter commentaries on the English rendition of specific words or phrases appearing in particular places (as opposed to general technical terms) that have attracted comment in the secondary literature are also provided in Volume 24. These minor commentaries are distinguished from those concerning general technical terms by the use of a superscript lower-case [t] in the place where the controversial translation appears. The corresponding set of annotations appears on pp. 105–33 of Volume 24, in chronological order, under the heading 'Annotations to Individual Translations'.

(3) Further interpolations in the translations of German words in square brackets are provided *ad hoc*, without superscript letters, for reasons that should be self-explanatory in each instance. For example, if a technical term which was referenced and discussed in a Note in Volume 24 appears again shortly afterwards in a way that illuminates the points discussed there, then it is silently referenced again. Some of these interpolations might seem odd to German-speaking readers, since no attempt is made to 'adjust' Freud's grammar to conform with the English translation (see the Preface to the Revised Edition, *RSE*, **1**, xxvi *n*. 1). The words in square brackets interpolated in the text are always exactly what Freud wrote.

(4) In a good few places, commentaries (of both types 1 and 2) are also provided in the Editors' introductory notes, appendices and footnotes to the text itself. These are indexed in Volume 24, on pp. 601–6, under the heading 'Notes on Terms and Their Uses'. Such commentaries are usually reserved for matters of translation that are likely to be of interest or value to the general reader, as opposed to those with a special interest in such technical matters.

The pagination of the original *Standard Edition* is provided also in the margins, in square brackets, to assist cross-referencing.

For the reasons explained in the 'Preface to the Revised Edition' (*RSE*, **1**, xxix), all differences between the *SE* and *RSE* are identified through light underscoring of the text. This device was considered necessary to make readers aware of the subtle and pervasive revisions of the translations. The same applies to the revisions of the editorial apparatus. This underscoring will hopefully be removed in later editions of the *RSE*, once the revised edition has become established as the canonical one.

The overarching policy here has been to underscore all differences between the *SE* and *RSE*, with minimal exceptions, in order to ensure transparency. The three categories of exceptions (i.e. the differences that are *not* underscored) are (a) changes that are purely typographical and/or absolutely stereotyped across Volumes 1–23, (b) changes in the location of Freud texts within or between volumes, and (c) all the changes to Volume 24.

The rationale behind (a) is that we wanted to avoid any subjective judgements by the Editor of the *RSE* as to what is and what is not 'significant'. For example, some but not all readers might consider alterations to Strachey's spelling, grammar and punctuation to be trivial, but the potential significance – however subtle – varies with context. The rationale behind (b) is that these changes are indicated in the 'List of Relocated Freud Material in the Revised Edition', which is provided in Volume 24. These changes are also mentioned in the revised (and therefore underscored) editorial notes to the texts themselves. The rationale behind (c) is that the *RSE* version of Volume 24 is so utterly different from the *SE* version that readers can safely consider the volume as a whole to be new.

The following changes were deemed purely typographical and absolutely stereotyped, and are therefore exempted from underscoring:

(1) Changes in type-size, font and spacing (since they are objectively insignificant).

(2) The marginalia – including page numbers – and the superscript ^{T}s and ^{t}s (since they always represent changes).

(3) Changed page numbers in the cross-references and indexes (this follows logically from point 2).

(4) Altered footnote numbers (since new footnotes are always identified by the fact that the notes themselves are underscored, and the knock-on effects for numbering are objectively insignificant).

(5) Changes in running headings (since they repetitively echo changes that are underscored in the main body of text).

(6) Change from the singular possessive 'Editor's' to the plural 'Editors'' (since this applies throughout and follows logically from the fact that, unlike the *SE*, the *RSE* has two editors). In the few instances where the Editor is referred to in the singular, it is always clear from the context whether this means Strachey or Solms or, in the case of Freud (1985*a* [1915]), Grubrich-Simitis.

(7) This preliminary 'Note on the Revised Translation' (since it is obviously added; it applies only to the *RSE*).

(8) Captions to the illustrations (since they always represent changes).

(9) Changes in editorial style (since they are stereotyped and therefore need only be identified once, namely here):

- The word 'and' in two-author citations becomes '&', and a comma is inserted between author name/s and the publication date (e.g. Freud & Breuer, 1895*d*).
- Abbreviations of months (e.g. 'Oct.') and chapters ('Chap.') are spelt out ('October', 'Chapter').
- '*The*' is added to all editorial references to '*Interpretation of Dreams*'.
- Title abbreviations conform to modern usage (e.g. *G.W.* becomes *GW*).
- Punctuation is positioned inside closing quotation marks (e.g. 'The Latin word slipped your memory.').

(10) Modernized hyphenation of words is underscored, but not for those terms that occur very repetitively in the text (since they are stereotyped and the list is limited enough for readers to memorize). Here is the list, which implies also the plural and other grammatical forms of these terms:

anxiety-dream	*becomes*	anxiety dream
anxiety-hysteria	*becomes*	anxiety hysteria
day-dream	*becomes*	daydream
death-wish	*becomes*	death wish
dream-content	*becomes*	dream content
dream-interpretation	*becomes*	dream interpretation
dream-thought	*becomes*	dream thought
ego-cathexis	*becomes*	ego cathexis
ego-libido	*becomes*	ego libido
love-object	*becomes*	love object
object-cathexis	*becomes*	object cathexis
object-choice	*becomes*	object choice
object-libido	*becomes*	object libido
object-love	*becomes*	object love
object-presentation	*becomes*	object presentation
object-relation	*becomes*	object relation
psycho-analysis	*becomes*	psychoanalysis
sound-presentation	*becomes*	sound presentation
super-ego	*becomes*	superego
thing-presentation	*becomes*	thing presentation
to-day	*becomes*	today
wish-fulfilment	*becomes*	wish fulfilment
word-presentation	*becomes*	word presentation

STUDIES ON HYSTERIA

BREUER & FREUD

(1893–95)

1895 Leipzig and Vienna: Deuticke. Pp. v + 269.
1909 2nd ed. Same publishers. (Unchanged, but with new Preface.) Pp. vii + 269.
1916 3rd ed. Same publishers. (Unchanged.) Pp. vii + 269.
1922 4th ed. Same publishers. (Unchanged.) Pp. vii + 269.
1925 *GS*, **1**, 3–238. (Omitting Breuer's contributions; with extra footnotes by Freud.)
1952 *GW*, **1**, 77–312. (Reprint of 1925.)
1975 *SA*, **Erg.**, 49–97. (Chapter 4 only.)
1987 *GW*, **Nachtr.**, 217–310. (Breuer's contribution only; with forewords to 1st and 2nd eds.)
1995 Frankfurt: S. Fischer. (Reprint of 1st ed.)

ENGLISH TRANSLATIONS

Studies in Hysteria

[x] 1909 *SPH*, 1–120. (1912, 2nd ed.; 1920, 3rd ed.; 1922, 4th ed.) (Tr. A. A. Brill.) (In part only: omitting the case histories of Fräulein Anna O., Frau Emmy von N. and Katharina, as well as Breuer's theoretical chapter.)

1936 New York: Nervous and Mental Diseases Publishing Co. (Monograph Series No. 61.) Pp. ix + 241. (Tr. A. A. Brill.) (Complete, except for omitting Freud's extra footnotes of 1925.)

2004 *PMC*. (Tr. Nicola Luckhurst.)

Studies on Hysteria

1955 *SE*, **2**. (Tr. J. & A. Strachey; based on 1925 German ed., but complete.)

1974 *PFL*, **3**. (Reprint of *SE* trans.)

The present translation is a revised and corrected reprint of the *SE* version. Additional editorial footnotes to the *RSE* translation draw heavily on subsequent research concerning the biographies of the patients in the *Studies* (without, however, revealing their identities; see *RSE*, **1**, xxx). The omission of Breuer's contributions from the two German collected editions (*GS* and *GW*) led to some necessary changes and additional footnotes in them, where references had been made by Freud in the original edition to the omitted portions. In these collected editions, too, the numbering of the case histories was altered, owing to the absence of that of Anna O. All these changes are disregarded in the present translation. – Abstracts both of the 'Preliminary Communication' and of the main volume were included in Freud's early collection of abstracts of his own works (1897*b*, Nos. XXIV and XXXI), *RSE*, **3**, 243 and 249.

Some Historical Notes on the Studies

The history of the writing of this book is known to us in some detail.

Breuer's treatment of Fräulein Anna O., on which the whole work was founded, took place between 1880 and 1882. By that time Josef Breuer (1842–1925) already had a high reputation in Vienna both as a physician with a large practice and as a man of scientific attainments, while Sigmund Freud (1856–1939) was only just qualifying as a [xi] doctor.[1] The two men had, however, already been friends for some years. The treatment ended early in June, 1882, and in the following November Breuer related the remarkable story to Freud, who (though at that time his main interests were centred on the anatomy of the nervous system) was greatly impressed by it. So much so, indeed, that, when, some three years later, he was studying in Paris under Charcot, he reported the case to him. 'But the great man showed no interest in my first outline of the subject, so that I never returned to it and allowed it to pass from my mind.' (*An Autobiographical Study*, 1925*d*, Chapter II; ibid., **20**, 16.)

Freud's studies under Charcot had centred largely on hysteria, and when he was back in Vienna in 1886 and settled down to establish a practice in nervous diseases, hysteria provided a large proportion of his clientele. To begin with he relied on such currently recommended methods of treatment as hydrotherapy, electrotherapy,

1 Much of the material in what follows is derived from Ernest Jones's life of Freud (1953, Vol. 1, and especially Chapter XI).

massage and the Weir Mitchell rest cure. But when these proved unsatisfactory his thoughts turned elsewhere. 'During the last few weeks', he writes to his friend Fliess on December 28, 1887, 'I have taken up hypnosis and have had all sorts of small but remarkable successes.' (Freud, 1950*a*, Letter 2.)[1] And he has given us a detailed account of one successful treatment of this kind (1893*a*). But the case of Anna O. was still at the back of his mind, and 'from the first', he tells us (1925*d*), 'I made use of hypnosis in *another* manner, apart from hypnotic suggestion' (*RSE*, **20**, 16). This 'other manner' was the cathartic method, which is the subject of the present volume.

The case of Frau Emmy von N. was the first one, as we learn from Freud (pp. 44 and 253 below), which he treated by the cathartic method.[2] In a footnote added to the book in 1924 he qualifies this and says it was the first case in which he made use of that method 'to a large extent' (p. 92); and it is true that at this early date he was still constantly employing hypnosis in the conventional manner – for giving direct therapeutic suggestions. At about this time, indeed, his interest in hypnotic suggestion was strong enough to lead him to translate one of Bernheim's books in 1888 and another in 1892, as well as to pay a visit of some weeks to the clinics of Liébeault and Bernheim [xii] at Nancy in the summer of 1889. The extent to which he was using therapeutic suggestion in the case of Frau Emmy is shown very clearly by his day-to-day report of the first two or three weeks of the treatment, reproduced by him from 'the notes which I made each evening' (p. 44). Thanks to the research of Ola Andersson (1979), we now know with reasonable certainty when Freud began this case (see Appendix A, p. 309); it was in May of 1889 – that is, about four months after he had first 'taken up hypnotism'. The treatment ended a year later, in the summer of 1890. There is a considerable gap before the date of the next case history (in chronological order, though not in order of presentation). This was the case of Fräulein Elisabeth von R., which began in the autumn of 1892 (p. 120) and which Freud describes (p. 123) as his 'first full-length analysis of a hysteria'. It was soon followed by that of Miss Lucy R., which began at the end of the same year (p. 94).[3] The remaining case, that of Katharina, began in the summer of 1893 (p. 110).[4] In the interval between 1889 and 1892 Freud certainly had experience with other cases. In particular, there was that of Frau Cäcilie M., whom he 'got to know far more thoroughly than any of the other patients mentioned in these studies' (p. 62 *n*.) but whose case could not be reported in detail owing to 'personal considerations'. She is, however, frequently discussed by Freud, as well as by Breuer, in the course of the volume, and we learn (p. 158) from Freud that 'it was the study of this remarkable case, jointly with Breuer, that led

1 All references to the Fliess correspondence in the *RSE* are to the 1950 edition, unless otherwise indicated. (See the Preface to the Revised Edition, *RSE*, **1**, xxx.)

2 A remark on p. 91 below almost seems to imply, on the other hand, that the case of Frau Cäcilie M. (mentioned below) preceded that of Frau Emmy. But this impression may perhaps be due to an ambiguity in the phrasing of the sentence.

3 It is to be noted that neither of these last two analyses had been more than started at the time of the publication of the 'Preliminary Communication'.

4 See also Fichtner & Hirschmüller (1985).

directly to the publication of our "Preliminary Communication"'.[1] In a letter to Fliess dated February 8, 1897, he even went so far as to remark: 'If you knew Cäcilie M., you would not doubt for a moment that only this woman could have been my teacher.'[2]

[xiii] The drafting of that epoch-making paper (which forms the first section of the present volume) had begun in June, 1892. A letter to Fliess of June 28 (Freud, 1950*a*, Letter 9) announces that 'Breuer has agreed that the theory of abreaction and the other findings on hysteria which we have arrived at jointly shall also be brought out jointly in a detailed publication.' 'A part of it', he goes on, 'which I at first wanted to write alone, is finished.' This 'finished' part of the paper is evidently referred to again in a letter to Breuer written on the following day, June 29, 1892 (Freud, 1941*a*; *RSE*, **1**, 175): 'The satisfaction with which I innocently handed you over those few pages of mine has given way to . . . uneasiness.' This letter goes on to give a very condensed summary of the proposed contents of the paper. On July 12, 1892, Freud reports to Fliess: 'My hysteria has, in Breuer's hands, become transformed, broadened, restricted, and in the process has partly evaporated. We are writing the thing jointly, each on his own working on several sections which he will sign, but still in complete agreement. No-one can yet say how it will turn out.'[3] Next we have a footnote added by Freud to his translation of a volume of Charcot's *Leçons du mardi* (Freud, 1892–94*a*; *RSE*, **1**, 165 f.), which gives, in three short paragraphs, a summary of the thesis of the 'Preliminary Communication' and refers to it as being 'begun'.[4] Besides this, two rather more elaborate drafts have survived.[5] The first (Freud, 1940*d*) of these (in

1 The question of when it was that Freud first began using the cathartic method is complicated still further by a statement made by him in 1916. The circumstances were these. At the International Medical Congress held in London in 1913, Pierre Janet had distinguished himself by making an absurdly ignorant and unfair attack on Freud and psychoanalysis. A reply was published by Ernest Jones in the *Journal of Abnormal Psychology*, **9** (1915), 400; and a German translation of this appeared in the *Int. Z. (ärztl.) Psychoan.*, **4** (1916), 34. In the course of his diatribe Janet had said that whatever was of the slightest value in psychoanalysis was entirely derived from his own early writings, and in traversing this assertion Jones had remarked that, though it was true that the actual publication of Breuer & Freud's findings was later than that of Janet's (which were published in 1889), the work on which their first paper was based preceded Janet's by several years. 'The cooperation of the two authors', he went on, 'antedated their first communication by as much as ten years, and it is expressly stated in the *Studien* that one of the cases there reported was treated by the cathartic method more than fourteen years before the date of the publication.' At this point in the German translation (ibid., 42) there is a footnote signed 'Freud', which runs as follows: 'I am obliged to correct Dr Jones on a point which is inessential so far as his argument is concerned but which is of importance to me. All that he says on the priority and independence of what was later named psychoanalytic work remains accurate, but it applies only to *Breuer's* achievements. My own collaboration began only in 1891–2. What I took over I derived not from Janet but from Breuer, as has often been publicly affirmed.' The date given here by Freud is a puzzling one: 1891 is two or three years too late for the beginning of the case of Frau Emmy and a year too early for that of Fräulein Elisabeth.

2 Masson trans., p. 229.

3 Masson trans., p. 32.

4 It is not possible to date this precisely; for, though Freud's Preface to his translation is dated 'June, 1892', the work came out in parts, the last of which could not have appeared before the end of May, 1894 (see *RSE*, **1**, 159–60). The footnote in question, however, appears on a relatively early page of the book, and may therefore be dated with fair certainty to the summer or autumn of 1892.

5 All of these drafts and summaries can be found in full in the first volume of the *Revised Standard Edition*.

Freud's handwriting, though stated to have been written jointly with Breuer) is dated 'End of November, 1892'. It deals with hysterical attacks and its contents were mostly included, though in different words, in Section IV of the 'Preliminary Communication' (p. 12 ff. below). One important paragraph, however, concerned with the 'principle of constancy', was unaccountably omitted, and in this volume the topic is treated only by Breuer, in the later part of the work (p. 175 ff.). Lastly there is a memorandum (Freud, 1941*b*) bearing the title 'III'. This is undated. It discusses 'hypnoid states' and hysterical dissociation, and is closely related to Section III of the published paper (p. 10 ff.). [xiv]

On December 18, 1892, Freud wrote to Fliess (1950*a*, Letter 11): 'I am delighted to be able to tell you that our theory of hysteria (reminiscence, abreaction, etc.) is going to appear in the *Neurologisches Centralblatt* on January 1, 1893, in the form of a detailed preliminary communication. It has meant a long battle with my partner.' The paper, bearing the date 'December, 1892', was actually published in two issues of the periodical: the first two sections on January 1 and the remaining three on January 15. The *Neurologisches Centralblatt* (which appeared fortnightly) was published in Berlin; and the 'Preliminary Communication' was almost immediately reprinted in full in Vienna in the *Wiener medizinische Blätter* (on January 19 and 26). On January 11, while the paper was only half-published, Freud gave a lecture on its subject matter at the Wiener medizinischer Club. A full shorthand report of the lecture, 'revised by the lecturer', appeared in the *Wiener medizinische Presse* on January 22 and 29 (**34**, 122–6 and 165–7). The lecture (Freud, 1893*h*; *RSE*, **3**, 27 ff.) covered approximately the same ground as the paper, but dealt with the material quite differently and in a much less formal manner.

The appearance of the paper seems to have produced little manifest effect in Vienna or Germany. In France, on the other hand, as Freud reports to Fliess in a letter of July 10, 1893 (1950*a*, Letter 13), it was favourably noticed by Janet, whose resistance to Freud's ideas was only to develop later. Janet included a long and highly laudatory account of the 'Preliminary Communication' in a paper on 'Some Recent Definitions of Hysteria' published in the *Archives de Neurologie* in June and July, 1893. He used this paper as the final chapter of his book *L'état mental des hystériques*, published in 1894. More unexpected, perhaps, is the fact that in April, 1893 – only three months after the publication of the 'Preliminary Communication' – a fairly full account of it was given by F. W. H. Myers at a general meeting of the Society for Psychical Research in London and was printed in their *Proceedings* in the following June. The 'Preliminary Communication' was also fully abstracted and discussed by Michell Clarke in *Brain* (1894, 125). The most surprising and unexplained reaction, however, was the publication in February and March, 1893, in the *Gaceta médica de Granada* (**11**, 105–11 and 129–35), of a complete translation of the 'Preliminary Communication', in Spanish. [xv]

The authors' next task was the preparation of the case material, and already on February 7, 1894, Freud spoke of the book as 'half-finished: what remains to be done is only a small minority of the case histories and two general chapters'. In a letter of May 21 he mentions that he is just writing the last case history, and on June 22 (1950*a*, Letter 19) he gives a list of what 'the book with Breuer' is to contain: 'five case histories, an essay by him, with which I have nothing at all to do, on the theories of

hysteria (summarizing and critical), and one by me on therapy which I have not started yet'. After this there was evidently a hold-up, for it is not until March 4, 1895 (1950*a*, Letter 22) that he writes to say that he is 'hurriedly working at the essay on the therapy of hysteria', which was finished by March 13. In another letter, of April 11, he tells him it will be out in three weeks. Finally, on April 20, he sends Fliess the second half of the proofs of the book.

The *Studies on Hysteria* seem to have been duly published in May, 1895, though the exact date is not stated. The book was unfavourably received in German medical circles; it was, for instance, very critically reviewed by Adolf von Strümpell, the well-known neurologist (*Dtsch. Z. Nervenheilk.*, 1896, 159). On the other hand, a non-medical writer, Alfred von Berger, later director of the Vienna Burgtheater, wrote appreciatively of it in the *Neue Freie Presse* (February 2, 1896). In England it was given a long and favourable notice in *Brain* (1896, 401) by Michell Clarke, and once again Myers showed his interest in it in an address of considerable length, first given in March, 1897, which was ultimately included in his *Human Personality* (1903).

[xvi] It was more than ten years before there was a call for a second edition of the book, and by that time the paths of its two authors had diverged. In May, 1906, Breuer wrote to Freud agreeing on a reprint, but there was some discussion about whether a new joint Preface was desirable. Further delays followed, and in the end, as will be seen below, two separate Prefaces were written. These bear the date of July, 1908, though the second edition was not actually published till 1909. The text was unaltered in this and the later editions of the book. But in 1924 Freud wrote some additional footnotes for the volume of his collected works containing his share of the *Studies* (published in 1925) and made one or two small changes in the text.

The Bearing of the Studies *on Psychoanalysis*

The *Studies on Hysteria* are usually regarded as the starting point of psychoanalysis. It is worth considering briefly whether and in what respects this is true. For the purposes of this discussion the question of the shares in the work attributable to the two authors will be left on one side for consideration below, and the book will be treated as a whole. An enquiry into the bearing of the *Studies* upon the subsequent development of psychoanalysis may be conveniently divided into two parts, though such a separation is necessarily an artificial one. To what extent and in what ways did the technical procedures described in the *Studies* and the clinical findings to which they led pave the way for the practice of psychoanalysis? To what extent were the theoretical views propounded here accepted into Freud's later doctrines?

The fact is seldom sufficiently appreciated that perhaps the most important of Freud's achievements was his invention of the first instrument for the scientific examination of the human mind. One of the chief fascinations of the present volume is that it enables us to trace the early steps of the development of that instrument. What it tells us is not simply the story of the overcoming of a succession of obstacles; it is the story

[xvii] of the *discovery* of a succession of obstacles that have to be overcome. Breuer's patient Anna O. herself demonstrated and overcame the first of these obstacles – the amnesia characteristic of the hysterical patient. When the existence of this amnesia was brought to light, there at once followed a realization that the patient's manifest mind was not the whole of it, that there lay behind it an *unconscious* mind (p. 41 ff. below).

It was thus plain from the first that the problem was not merely the investigation of *conscious* mental processes, for which the ordinary methods of enquiry used in everyday life would suffice. If there were also *unconscious* mental processes, some special instrument was clearly required. The obvious instrument for this purpose was hypnotic suggestion – hypnotic suggestion used, not for directly therapeutic purposes, but to persuade the patient to produce material from the unconscious region of the mind. With Anna O. only slight use of this instrument seemed necessary. She produced streams of material from her 'unconscious', and all Breuer had to do was to sit by and listen to them without interrupting her. But this was not so easy as it sounds, and the case history of Frau Emmy shows at many points how difficult it was for Freud to adapt himself to this new use of hypnotic suggestion and to listen to all that the patient had to say without any attempt at interference or at making shortcuts (e.g. pp. 54 *n.* and 56 *n.* 1 below). Not all hysterical patients, moreover, were so amenable as Anna O.; the deep hypnosis into which she fell, apparently of her own accord, was not so readily obtained with everyone. And here came a further obstacle: Freud tells us that he was far from being an adept at hypnotism. He gives us several accounts in this book (e.g. p. 95 ff.) of how he circumvented this difficulty, of how he gradually gave up his attempts at bringing about hypnosis and contented himself with putting his patients into a state of 'concentration' and with the occasional use of pressure on the forehead. But it was the abandonment of hypnotism that widened still further his insight into mental processes. It revealed the presence of yet another obstacle – the patients' 'resistance' to the treatment (pp. 136 f. and 238 ff.), their unwillingness to cooperate in their own cure. How was this unwillingness to be dealt with? Was it to be shouted down or suggested away? Or was it, like other mental phenomena, simply to be investigated? Freud's choice of this second path led him directly into the uncharted world which he was to spend his whole life in exploring.

In the years immediately following the *Studies* Freud abandoned more and more [xviii]
of the machinery of deliberate suggestion (cf. p. 98 *n.* 1) and came to rely more and more on the patient's flow of 'free associations'. The way was opened up to the analysis of dreams. Dream analysis enabled him, in the first place, to obtain an insight into the workings of the 'primary process' in the mind and the ways in which it influenced the products of our more accessible thoughts, and he was thus put in possession of a new technical device – that of 'interpretation'. But dream analysis made possible, in the second place, his own self-analysis, and his consequent discoveries of infantile sexuality and the Oedipus complex. All these things, apart from some slight hints,[1] still lay ahead. But he had already, in the last pages of this volume, come up against one further obstacle in the investigator's path – the 'transference' (p. 268 ff.). He had already had a glimpse of its formidable nature and had even, perhaps, already begun to recognize that it was to prove not only an obstacle but also another major instrument of psychoanalytic technique.

The main theoretical position adopted by the authors of the 'Preliminary Communication' seems, on the surface, a simple one. They hold that, in the normal course of things, if an experience is accompanied by a large amount of 'affect', that affect is either 'discharged' in a variety of conscious reflex acts or becomes gradually worn

1 See, for instance, the remarks on dreams in a footnote on p. 62 below, and a hint at the notion of free association on p. 51.

away by association with other conscious mental material. In the case of hysterical patients, on the other hand (for reasons which we shall mention in a moment), neither of these things happens. The affect remains in a 'strangulated' state, and the memory of the experience to which it is attached is cut off from consciousness. The affective memory is thereafter manifested in hysterical symptoms, which may be regarded as 'mnemic symbols' – that is to say, as symbols of the suppressed memory (p. 80 below). Two principal reasons are suggested to explain the occurrence of this pathological outcome. One is that the original experience took place while the subject was in a particular dissociated state of mind described as 'hypnoid'; the other is that the experience was one which the subject's 'ego' regarded as 'incompatible' with
[xix] itself and which had therefore to be 'fended off'. In either case the therapeutic effectiveness of the 'cathartic' procedure is explained on the same basis: if the original experience, along with its affect, can be brought into consciousness, the affect is by that very fact discharged or 'abreacted', the force that has maintained the symptom ceases to operate, and the symptom itself disappears.

This all seems quite straightforward, but a little reflection shows that much remains unexplained. Why should an affect need to be 'discharged'? And why are the consequences of its not being discharged so formidable? These underlying problems are not considered at all in the 'Preliminary Communication', though they had been alluded to briefly in two of the posthumously published drafts (1941*a* and 1940*d*) and a hypothesis to provide an explanation of them was already in existence. Oddly enough, this hypothesis was actually stated by Freud in his lecture of January 11, 1893 (see p. xvii), in spite of its omission from the 'Preliminary Communication' itself. He again alluded to it in the last two paragraphs of his first paper on 'The Neuropsychoses of Defence' (1894*a*), *RSE*, **3**, 56, where he specifically states that it underlay the theory of abreaction in the 'Preliminary Communication' of a year earlier. But this basic hypothesis was first formally produced and given a name in 1895 in the second section of Breuer's contribution to the present volume (p. 171 ff.). It is curious that this, the most fundamental of Freud's theories, was first fully discussed by Breuer (attributed by him, it is true, to Freud), and that Freud himself, though he occasionally reverted to its subject matter (as in the early pages of his paper on 'Drives and their Vicissitudes', 1915*c*; *RSE*, **14**), did not mention it explicitly till he wrote *Beyond the Pleasure Principle* (1920*g*), ibid., **18**. He did, as we now know, refer to the hypothesis by name in a communication to Fliess of uncertain date, possibly 1894 (Draft D, 1950*a*), and he considered it fully, though under another name (see below, p. xxiii), in the 'Project for a Scientific Psychology' which he wrote a few months after the publication of the *Studies*. But it was not until fifty-five years later (1950*a*) that Draft D and the 'Project' saw the light of day.

The 'principle of constancy' (for this was the name given to the hypothesis) may be defined in the terms used by Freud himself in *Beyond the Pleasure Principle*: 'The
[xx] mental apparatus endeavours to keep the quantity of excitation present in it as low as possible or at least to keep it constant.' (*RSE*, **18**, 8–9.) Breuer states it below (p. 175) in very similar terms, but with a neurological twist, as a 'tendency to keep intracerebral excitation constant'.[1] In his discussion on p. 179 ff., he argues that the affects owe their

1 Freud's statement of the principle in the lecture of January 11, 1893, was as follows: 'If a person experiences a psychical impression, something in his nervous system which we will for the moment call the sum of excitation is increased. Now in every individual there exists a tendency to diminish this sum of excitation once more, in order to preserve his health . . .' (Freud, 1893*h*; *RSE*, 3, 34–5).

importance in the aetiology of hysteria to the fact that they are accompanied by the production of large quantities of excitation, and that these in turn call for discharge in accordance with the principle of constancy. Similarly, too, traumatic experiences owe their pathogenic force to the fact that they produce quantities of excitation too large to be dealt with in the normal way. Thus the essential theoretical position underlying the *Studies* is that the clinical necessity for abreacting affect and the pathogenic results of its becoming strangulated are explained by the much more general tendency (expressed in the principle of constancy) to keep the quantity of excitation constant.

It has often been thought that the authors of the *Studies* attributed the phenomena of hysteria only to traumas and to ineradicable memories of them, and that it was not until later that Freud, after shifting the emphasis from infantile traumas to infantile phantasies, arrived at his momentous 'dynamic' view of the processes of the mind. It will be seen, however, from what has just been said, that a dynamic hypothesis in the shape of the principle of constancy already underlay the theory of trauma and abreaction. And when the time came for widening the horizon and for attributing a far greater importance to drives as contrasted with experience, there was no need to modify the basic hypothesis. Already, indeed, Breuer points out the part played by 'the organism's major physiological needs and drives' in causing increases in excitation which call for discharge (p. 177 below), and emphasizes the importance of the 'sexual drive' as 'the most powerful source of persisting accretions of excitation (and consequently of neuroses)' (p. 179). Moreover, the whole notion of conflict and the repression of incompatible ideas is explicitly based on the occurrence of unpleasur- [xxi]
able increases of excitation. This leads to the further consideration that, as Freud points out in *Beyond the Pleasure Principle* (*RSE*, **18**, 7 ff.), the 'pleasure principle' itself is closely bound up with the principle of constancy. He even goes further and declares (ibid., 59) that the pleasure principle 'is a tendency operating in the service of a function whose business it is to free the mental apparatus entirely from excitation or to keep the amount of excitation in it constant or to keep it as low as possible'. The 'conservative' character which Freud attributes to the drives in his later works, and the 'compulsion to repeat', are also seen in the same passage to be manifestations of the principle of constancy; and it becomes clear that the hypothesis on which these early *Studies on Hysteria* were based was still being regarded by Freud as fundamental in his very latest speculations.

The Divergences between the Two Authors

We are not concerned here with the personal relations between Breuer and Freud, which have been fully described in the first volume of Ernest Jones's biography and elsewhere; but it will be of interest to discuss briefly their *scientific* differences. The existence of such differences was openly mentioned in the Preface to the first edition, and they were often enlarged upon in Freud's later publications. But in the book itself, oddly enough, they are far from prominent; and even though the 'Preliminary Communication' is the only part of it with an explicitly joint authorship, it is not easy to assign with certainty the responsibility for the origin of the various component elements of the work as a whole.

We can no doubt safely attribute to Freud the later technical developments, together with the vital theoretical concepts of resistance, defence and repression which arose from them. It is easy to see from the account given on p. 238 ff. below

how these concepts followed from the replacement of hypnosis with the pressure technique. Freud himself, in his 'History of the Psychoanalytic Movement' (1914*d*), *RSE*, **14**, 13, declares that 'the theory of repression is the cornerstone on which the
[xxii] whole structure of psychoanalysis rests', and gives the same account as he does here of the way in which it was arrived at. He also asserts his belief that he reached this theory independently, and the history of the discovery amply confirms that belief. He remarks in the same passage that a hint at the notion of repression is to be found in Schopenhauer (1819), whose works, however, he read only late in life; and it has recently been pointed out that the word '*Verdrängung*' ('repression') occurs in the writings of the early nineteenth-century psychologist Herbart (1824) whose ideas carried great weight with many of those in Freud's environment, and particularly with his immediate teacher in psychiatry, Meynert. But no such suggestions detract in any significant degree from the originality of Freud's theory, with its empirical basis, which found its first expression in the 'Preliminary Communication' (p. 9).

As against this, there can be no question that Breuer originated the notion of 'hypnoid states', to which we shall return shortly, and it seems possible that he was responsible for the terms 'catharsis' and 'abreaction'.

But many of the theoretical conclusions in the *Studies* must have been the product of discussions between the two authors during their years of collaboration, and Breuer himself comments (pp. 165–6) on the difficulty of determining priority in such cases. Apart from the influence of Charcot, on which Freud never ceased insisting, it must be remembered, too, that both Breuer and Freud owed a fundamental allegiance to the school of Helmholtz, of which their teacher, Ernst Brücke, was a prominent member. Much of the underlying theory in the *Studies on Hysteria* is derived from the doctrine of that school that all natural phenomena are ultimately explicable in terms of physical and chemical forces.[1]

We have already seen (p. xx) that, though Breuer was the first to mention the 'principle of constancy' by name, he attributes the hypothesis to Freud. He similarly
[xxiii] attaches Freud's name to the term 'conversion', but (as is explained below, p. 184 *n.*) Freud himself has declared that this applies only to the *word* and that the concept was arrived at jointly. On the other hand there are a number of highly important concepts which seem to be properly attributable to Breuer: the notion of hallucination being a 'retrogression' from imagery to perception (p. 169), the thesis that the functions of perception and memory cannot be performed by the same apparatus (p. 168 *n.*), and finally, and most surprisingly, the distinction between bound (tonic) and unbound (mobile) psychical energy and the correlated distinction between primary and secondary psychical processes (p. 173 *n.*).

The use of the term '*Besetzung*' ('cathexis'), which makes its first appearance on p. 79 in the sense that was to become so familiar in psychoanalytic theory, is probably to be attributed to Freud. The idea of the whole or a part of the mental apparatus carrying a charge of energy is, of course, presupposed by the principle of constancy.

1 The various influences that may possibly have played a part in determining Freud's views are very fully discussed by Ernest Jones (1953, **1**, 44 ff. and 407 ff.). In addition to the names referred to in the text above, special mention should be made of the psychophysicist Fechner, to whom Freud himself acknowledged his indebtedness in the fifth chapter of his *Autobiographical Study* (1925*d*), *RSE*, **20**, 52. See also Freud, 1920*g*; ibid., **18**, where even the principle of constancy seems to be attributed to Fechner. The influence of Hughlings Jackson, too, cannot be overestimated.

And though the actual term that was to be the standard one first came into use in this volume, the idea had been expressed earlier by Freud in other forms. Thus we find him using such phrases as '*mit Energie ausgestattet*' ('supplied with energy') (1895*b*), '*mit einer Erregungssumme behaftet*' ('loaded with a sum of excitation') (1894*a*), '*munie d'une valeur affective*' ('provided with a quota of affect') (1893*c*), '*Verschiebungen von Erregungssummen*' ('displacements of sums of excitation') (1941*a* [1892]) and, as long ago as in his Preface to his first translation of Bernheim (1888–89*a*), '*Verschiebungen von Erregbarkeit im Nervensystem*' ('displacements of excitability in the nervous system').

But this last quotation is a reminder of something of great importance that may very easily be overlooked. There can be no doubt that at the time of the publication of the *Studies* Freud regarded the term 'cathexis' as a purely physiological one. This is proved by the definition of the term given by him in Part I, Section 2, of his 'Project for a Scientific Psychology' by which (as is shown in the Fliess letters) his mind was already occupied, and which was written only a few months later. There, after giving an account of the recently discovered neurological entity, the 'neuron', he goes on: 'If we combine this account of the neurons with the conception of the *Qη* theory, we arrive at the idea of a *cathected* neuron filled with a certain *Qη* while at other times it may be empty.' (*RSE*, **1**, 322.) The neurological bias of Freud's theories at this period [xxiv] is further shown by the form in which the principle of constancy is stated in the same passage in the 'Project'. It is given the name of 'the principle of neuronal inertia' and is defined as asserting 'that neurons tend to divest themselves of *Q*', ibid., **1**, 320. A remarkable paradox is thus revealed. Breuer, as will be seen (p. 165 below), declares his intention of treating the subject of hysteria on purely psychological lines: 'In what follows little mention will be made of the brain and none whatever of molecules. Psychical processes will be dealt with in the language of psychology.' But in fact his theoretical chapter is largely concerned with 'intracerebral excitations' and with parallels between the nervous system and electrical installations. On the other hand, Freud was devoting all his energies to explaining mental phenomena in physiological and chemical terms. Nevertheless, as he himself somewhat ruefully confesses (p. 143), his case histories read like short stories and his analyses are psychological ones.

The truth is that in 1895 Freud was at a halfway stage in the process of moving from physiological to psychological explanations of psychopathological states. On the one hand he was proposing what was broadly speaking a chemical explanation of the 'actual' neuroses – neurasthenia and anxiety neurosis – in his two papers on anxiety neurosis (1895*b* and 1895*f*), *RSE*, **3**, and on the other hand he was proposing an essentially psychological explanation – in terms of 'defence' and 'repression' – of hysteria and obsessions – in his two papers on 'The Neuropsychoses of Defence' (1894*a* and 1896*b*), ibid., **3**. His earlier training and career as a neurologist led him to resist the acceptance of psychological explanations as ultimate; and he was engaged in devising a complicated structure of hypotheses intended to make it possible to describe mental events in purely neurological terms. This attempt culminated in the 'Project' and was not long afterwards abandoned. To the end of his life, however, Freud continued to adhere to the chemical aetiology of the 'actual neuroses' and to believe that a physical explanation of *all* mental phenomena might ultimately be found. But in the meantime he gradually came round to the view expressed by

Breuer that psychical processes can only be dealt with in the language of psychology. It was not until 1905 (in his book on *Jokes*, Chapter V; *RSE*, **8**) that he first explicitly
[xxv] repudiated all intention of using the term 'cathexis' in any but a psychological sense and all attempts at equating nerve tracts or neurons with paths of mental association.[1]

What, however, were the essential scientific differences between Breuer and Freud? In his *Autobiographical Study* (1925*d*) Freud says that the first of these related to the aetiology of hysteria and could be described as '"hypnoid hysteria" versus "neuroses of defence"' (ibid., **20**, 19). But once again, in this volume itself the issue is less clear-cut. In the joint 'Preliminary Communication' both aetiologies are accepted (p. 9 f. below). Breuer, in his theoretical chapter, evidently lays most emphasis on hypnoid states (p. 191 ff.), but he also stresses the importance of 'defence' (pp. 191 and 210), though a little half-heartedly. Freud seems to accept the notion of 'hypnoid states' in his 'Katharina' case history (p. 113)[2] and, less definitely, in that of Fräulein Elisabeth (p. 149 *n.*). It is only in his final chapter that his scepticism begins to be apparent (p. 254 f.). In a paper on 'The Aetiology of Hysteria' published in the following year (1896*c*), *RSE*, **3**, this scepticism is still more openly expressed, and in a footnote to his 'Dora' case history (1905*e*) he declares that the term 'hypnoid states' is 'superfluous and misleading' and that the hypothesis 'sprang entirely from the initiative of Breuer' (ibid., **7**, 25 *n.* 2).

But the chief difference of opinion between the two authors upon which Freud later insisted concerned the part played by sexual impulses in the causation of hysteria. Here too, however, the *expressed* difference will be found less clear than would be expected. Freud's belief in the sexual origin of hysteria can be inferred plainly enough from the discussion in his chapter on psychotherapy (p. 229 ff.), but he nowhere asserts, as he was later to do, that in cases of hysteria a sexual aetiology was
[xxvi] invariably present.[3] On the other hand, Breuer speaks at several points in the strongest terms of the importance of the part played by sexuality in the neuroses, particularly in the long passage on pp. 218–20. He says, for instance (as has already been remarked, p. xxi), that 'the sexual drive is undoubtedly the most powerful source of persisting accretions of excitation (and consequently of neuroses)' (p. 179), and declares (p. 219) that 'the great majority of severe neuroses in women have their origin in the marriage bed'.

1 The insecurity of the neurological position which Freud was still trying to maintain in 1895 is emphasized by the correction that he felt obliged to make thirty years later in the very last sentence of the book. In 1895 he used the word '*Nervensystem*' ('nervous system'); in 1925 he replaced it with '*Seelenleben*' ('mental life'). Yet what was ostensibly a momentous change did not in the least affect the meaning of the sentence. The old neurological vocabulary had already been no more than a husk at the time when Freud penned the words. This reflects a deeper truth: from the mid-1890s onwards, Freud seemed to treat physiology and psychology as providing parallel observational perspectives on the underlying functions of the mental apparatus. This ultimate focus on the *functional* architecture was explicitly declared in Chapter VII of *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 479, and given the name 'metapsychology'.

2 As he already had in his first paper on 'The Neuropsychoses of Defence' (1894*a*), ibid., **3**, and in the memorandum 'III' (1941*b*), almost certainly written in 1892, ibid., **1** (see above, p. xvii).

3 Indeed, in the fourth of his *Five Lectures* (1910*a*), *RSE*, **11**, he categorically asserts that at the time of the publication of the *Studies* he did not yet believe that this was so. The first public expression of this conviction seems to have been given in his October lecture 'On Hysteria' (1895*g*), p. 291 ff. below. (See also the Editors' Introduction to that paper, p. 289.)

It seems as though, in order to find a satisfactory explanation of the dissolution of this scientific partnership, we should have to look behind the printed words. Freud's letters to Fliess show Breuer as a man full of doubts and reservations, always insecure in his conclusions. There is an extreme instance of this in a letter of November 8, 1895 (1950*a*, Letter 35), written shortly after Freud delivered his (1895*g*) lecture 'On Hysteria', about six months after the publication of the *Studies*: 'Not long ago Breuer made a big speech to the physicians' society about me, putting himself forward as a convert to belief in the sexual aetiology [of the neuroses]. When I thanked him privately for this he spoilt my pleasure by saying: "But all the same I *don't* believe it!" Can you make head or tail of that? I cannot.' Something of the kind can be read between the lines of Breuer's contributions to the *Studies*, and we have the picture of a man half-afraid of his own remarkable discoveries. It was inevitable that he should be even more disconcerted by the premonition of still more unsettling discoveries yet to come; and it was inevitable that Freud in turn should feel hampered and irritated by his yoke-fellow's uneasy hesitations.

It would be tedious to enumerate the many passages in Freud's later writings in which he refers to the *Studies on Hysteria* and to Breuer; but a few quotations will illustrate the varying emphasis in his attitude to them.

In the numerous short accounts of his therapeutic methods and psychological theories which he published during the years immediately succeeding the issue of the *Studies*, he was at pains to bring out the differences between 'psychoanalysis' and the cathartic method – the technical innovations, the extension of his procedure to [xxvii]
neuroses other than hysteria, the establishment of the motive of 'defence', the insistence on a sexual aetiology and, as we have already seen, the final rejection of 'hypnoid states'. When we reach the first series of Freud's major works – the volumes on dreams (1900*a*), on parapraxes (1901*b*), on jokes (1905*c*) and on sexuality (1905*d*) – there is naturally little or no retrospective material; and it is not until the five lectures at Clark University (1910*a*) that we find any extensive historical survey. In those lectures Freud appeared anxious to establish the continuity between his work and Breuer's. The whole of the first lecture and much of the second are devoted to a summary of the *Studies*, and the impression given was that not Freud but Breuer was the true founder of psychoanalysis.

The next long retrospective survey, in the 'History of the Psychoanalytic Movement' (1914*d*), *RSE*, **14**, was in a very different key. The whole paper, of course, was polemical in its intent and it is not surprising that in sketching the early history of psychoanalysis Freud stressed his differences from Breuer rather than his debts to him, and that he explicitly retracted his view of him as the originator of psychoanalysis. In this paper, too, Freud dilated on Breuer's inability to face the sexual transference and revealed an 'untoward event' which ended the analysis of Anna O. (p. 37 *n*. 1 below).

Next came what seems almost like an *amende* – it has already been mentioned on p. xxii – the unexpected attribution to Breuer of the distinction between bound and unbound psychical energy and between the primary and secondary processes. There had been no hint of this attribution when these hypotheses were originally introduced by Freud (in *The Interpretation of Dreams*, 1900*a*; *RSE*, **4–5**); it was first made in a footnote to Section V of the metapsychological paper on 'The Unconscious' (1915*e*), ibid., **14**, 165 *n*. 1, and repeated in *Beyond the Pleasure Principle* (1920*g*),

RSE, **18**, 26–7 and 30 f. Not long after the last of these there were some appreciative sentences in an article contributed by Freud to Marcuse's *Handwörterbuch* (1923*a*), ibid., **18**, 230: 'In a theoretical section of the *Studies* Breuer brought forward some speculative ideas about the processes of excitation in the mind. These ideas determined the direction of future lines of thought. . . .' In somewhat the same vein Freud wrote a little later in a contribution to an American publication (1924*f*), ibid., **19**, 192:
[xxviii] 'The cathartic method was the immediate precursor to psychoanalysis; and, in spite of every extension of experience and of every modification of theory, is still contained within it as its nucleus.'

Freud's next long historical survey, *An Autobiographical Study* (1925*d*), ibid., **20**, 18, seemed once more to withdraw from the joint work: 'If the account I have so far given', he wrote, 'has led the reader to expect that the *Studies on Hysteria* must, in all essentials of their material content, be the product of Breuer's mind, that is precisely what I myself have always maintained. . . . As regards the *theory* put forward in the book, I was partly responsible, but to an extent which it is today no longer possible to determine. That theory was in any case unpretentious and hardly went beyond the direct description of the observations.' He added that 'it would have been difficult to guess from the *Studies on Hysteria* what an importance sexuality has in the aetiology of the neuroses' (ibid., 19), and went on once more to describe Breuer's unwillingness to recognize that factor.

It was soon after this that Breuer died, and it is perhaps appropriate to end this introduction to the joint work with a quotation from Freud's obituary of his collaborator (1925*g*), ibid., **19**, 288. After remarking on Breuer's reluctance to publish the *Studies* and declaring that his own chief merit in connection with them lay in his having persuaded Breuer to agree to their appearance, he proceeded:

> At the time when he submitted to my influence and was preparing the *Studies* for publication, his judgement of their significance seemed to be confirmed. 'I believe', he told me, 'that this is the most important thing we two have to give the world.'
>
> Besides the case history of his first patient Breuer contributed a theoretical paper to the *Studies*. It is very far from being out of date; on the contrary, it conceals thoughts and suggestions which have even now not been turned to sufficient account. Anyone immersing himself in this speculative essay will form a true impression of the mental build of this man, whose scientific interests were, alas, turned in the direction of our psychopathology during only one short episode of his long life.

PREFACE TO THE FIRST EDITION

In 1893 we published a 'Preliminary Communication'[1] on a new method of examining and treating hysterical phenomena. To this we added as concisely as possible the theoretical conclusions at which we had arrived. We are here reprinting this 'Preliminary Communication' to serve as the thesis which it is our purpose to illustrate and prove. [xxix]

We have appended to it a series of case histories, the selection of which could not unfortunately be determined on purely scientific grounds. Our experience is derived from private practice in an educated and literate social class, and the subject matter with which we deal often touches upon our patients' most intimate lives and histories. It would be a grave breach of confidence to publish material of this kind, with the risk of the patients being recognized and their acquaintances becoming informed of facts which were confided only to the physician. It has therefore been impossible for us to make use of some of the most instructive and convincing of our observations. This of course applies especially to all those cases in which sexual and marital relations play an important aetiological part. Thus it comes about that we are able to produce only very incomplete evidence in favour of our view that sexuality seems to play a principal part in the pathogenesis of hysteria as a source of psychical traumas and as a motive for 'defence' [*'Abwehr'*][T] – that is, for repressing [*Verdrängung*][T] ideas [*Vorstellungen*][T] from consciousness. It is precisely observations of a markedly sexual nature that we have been obliged to leave unpublished.

The case histories are followed by a number of theoretical reflections, and in a final chapter on therapeutics the technique of the 'cathartic method' is propounded, just as it has grown up under the hands of the neurologist.

If at some points divergent and indeed contradictory opinions are expressed, this is not to be regarded as evidence of any fluctuation in our

1 'On the Psychical Mechanism of Hysterical Phenomena', *Neurologisches Centralblatt*, 1893, Nos. 1 and 2.

views [*Auffassung*][T]. It arises from the natural and justifiable differences
[xxx] between the opinions of two observers who are agreed upon the facts and their basic reading of them, but who are not invariably at one in their interpretations and conjectures.

J. BREUER, S. FREUD
April, 1895

PREFACE TO THE SECOND EDITION

The interest which, to an ever-increasing degree, is being directed to psychoanalysis seems now to be extending to these *Studies on Hysteria*. The publisher desires to bring out a new edition of the book, which is at present out of print. It appears now in a reprint, without any alterations, though the opinions and methods which were put forward in the first edition have since undergone far-reaching and profound developments. So far as I personally am concerned, I have since that time had no active dealings with the subject; I have had no part in its important development and I could add nothing fresh to what was written in 1895. So I have been able to do no more than express a wish that my two contributions to the volume should be reprinted without alteration. [xxxi]

BREUER

As regards my share of the book, too, the only possible decision has been that the text of the first edition shall be reprinted without alteration. The developments and changes in my views during the course of thirteen years of work have been too far-reaching for it to be possible to attach them to my earlier exposition without entirely destroying its essential character. Nor have I any reason for wishing to eliminate this evidence of my initial views. Even today I regard them not as errors but as valuable first approximations to knowledge which could only be fully acquired after long and continuous efforts. The attentive reader will be able to detect in the present book the germs of all that has since been added to the theory of catharsis: for instance, the part played by psychosexual factors and infantilism, the importance of dreams and of unconscious symbolism. And I can give no better advice to anyone interested in the development of catharsis into psychoanalysis than to begin with *Studies on Hysteria* and thus follow the path which I myself have trodden.

FREUD

Vienna, July, 1908

I

PRELIMINARY COMMUNICATION

(1893)

(BREUER & FREUD)

I

ON THE PSYCHICAL MECHANISM OF HYSTERICAL PHENOMENA: PRELIMINARY COMMUNICATION (1893)[1]

(BREUER & FREUD)

I

A chance observation has led us, over a number of years, to investigate a [3]
great variety of different forms and symptoms of hysteria, with a view to discovering their precipitating cause – the event which provoked the first occurrence, often many years earlier, of the phenomenon in question. In the great majority of cases it is not possible to establish the point of origin by a simple interrogation of the patient, however thoroughly it may be carried out. This is in part because what is in question is often some experience which the patient dislikes discussing; but principally because he is genuinely unable to recollect it and often has no suspicion of the causal connection between the precipitating event and the pathological phenomenon. As a rule it is necessary to hypnotize the patient and to arouse his memories under hypnosis of the time at which the symptom made its first appearance; when this has been done, it becomes possible to demonstrate the connection in the clearest and most convincing fashion.

This method of examination has in a large number of cases produced results which seem to be of value alike from a theoretical and a practical point of view.

They are valuable theoretically because they have taught us that exter- [4]
nal events determine the pathology of hysteria to an extent far greater than is known and recognized. It is of course obvious that in cases of

1 [As explained above in the Preface to the first edition, this first chapter had appeared originally as a separate paper in 1893. It was reprinted not only in the present book, but also in the first of Freud's collected volumes of his shorter works, *Sammlung kleiner Schriften zur Neurosenlehre* (1906). The following footnote was appended to this latter reprint: 'Also printed as an introduction to *Studies on Hysteria*, 1895, in which Josef Breuer and I further developed the views expressed here and illustrated them by case histories.']

'traumatic' hysteria what provokes the symptoms is the accident. The causal connection is equally evident in hysterical attacks when it is possible to gather from the patient's utterances that in each attack he is hallucinating the same event which provoked the first one. The situation is more obscure in the case of other phenomena.

Our experiences have shown us, however, that the most various symptoms, which are ostensibly spontaneous and, as one might say, idiopathic products of hysteria, are just as strictly related to the precipitating trauma as the phenomena to which we have just alluded and which exhibit the connection quite clearly. The symptoms which we have been able to trace back to precipitating factors of this sort include neuralgias and anaesthesias of very various kinds, many of which had persisted for years, contractures and paralyses, hysterical attacks and epileptoid convulsions, which every observer regarded as true epilepsy, *petit mal* and disorders in the nature of tic, chronic vomiting and anorexia, carried to the pitch of rejection of all nourishment, various forms of disturbance of vision, constantly recurrent visual hallucinations, etc. The disproportion between the many years' duration of the hysterical symptom and the single occurrence which provoked it is what we are accustomed invariably to find in traumatic neuroses. Quite frequently it is some event in childhood that sets up a more or less severe symptom which persists during the years that follow.

The connection is often so clear that it is quite evident how it was that the precipitating event produced this particular phenomenon rather than any other. In that case the symptom has quite obviously been determined by the precipitating cause. We may take as a very commonplace instance a painful [*schmerzlicher*] emotion arising during a meal but suppressed at the time, and then producing nausea and vomiting which persists for months in the form of hysterical vomiting. A girl, watching beside a sick-bed in a torment of anxiety, fell into a twilight state and had a terrifying hallucination, while her right arm, which was hanging over the back of her chair, went to sleep; from this there developed a paresis of the same arm accompanied by contracture and anaesthesia. She tried to pray but could find no words; at length she succeeded in repeating a children's
[5] prayer in English. When subsequently a severe and highly complicated hysteria developed, she could only speak, write and understand English, while her native language remained unintelligible to her for eighteen months.[1] – The mother of a very sick child, which had at last fallen asleep, concentrated her whole willpower on keeping still so as not to waken it.

1 [This patient is the subject of the first case history; see below, p. 19 ff.]

Precisely on account of her intention she made a 'clacking' noise with her tongue. (An instance of 'hysterical counterwill'.) This noise was repeated on a subsequent occasion on which she wished to keep perfectly still; and from it there developed a tic which, in the form of a clacking with the tongue, occurred over a period of many years whenever she felt excited.[1] – A highly intelligent man was present while his brother had an ankylosed hip joint extended under an anaesthetic. At the instant at which the joint gave way with a crack, he felt a violent pain in his own hip joint, which persisted for nearly a year. – Further instances could be quoted.

In other cases the connection is not so simple. It consists only in what might be called a 'symbolic' relation between the precipitating cause and the pathological phenomenon – a relation such as healthy people form in dreams. For instance, a neuralgia may follow upon mental pain or vomiting upon a feeling of moral disgust. We have studied patients who used to make the most copious use of this sort of symbolization.[2] In still other cases it is not possible to understand at first sight how they can be determined in the manner we have suggested. It is precisely the typical hysterical symptoms which fall into this class, such as hemianaesthesia, contraction of the field of vision, epileptiform convulsions, and so on. An explanation of our views on this group must be reserved for a fuller discussion of the subject.

Observations such as these seem to us to establish an analogy between the pathogenesis of common hysteria and that of traumatic neuroses, and to justify an extension of the concept of traumatic hysteria. In traumatic neuroses the operative cause of the illness is not the trifling physical [6]
injury but the affect of fright [*Schreckaffekt*] – the psychical trauma. In an analogous manner, our investigations reveal, for many, if not for most, hysterical symptoms, precipitating causes which can only be described as psychical traumas. Any experience which calls up distressing affects – such as those of fright, anxiety [*Angst*][T], shame or psychical[3] pain – may operate as a trauma of this kind; and whether it in fact does so depends naturally enough on the susceptibility of the person affected (as well as on another condition which will be mentioned later). In the case of common hysteria it not infrequently happens that, instead of a single, major trauma, we find a number of partial traumas forming a *group* of provoking causes. These have only been able to exercise a traumatic effect

1 [This patient is the subject of the second case history; see below, p. 44 ff. These episodes are also treated at some length in 'A Case of Successful Treatment by Hypnotism' (Freud, 1892–93*a*), where the concept of 'hysterical counterwill' is also discussed; *RSE*, **1**, 145 ff.]

2 [See the account of Frau Cäcilie M., p. 156 ff. below.]

3 [Misprinted as 'physical' in the *SE*.]

by summation and they belong together insofar as they are in part components of a single story of suffering. There are other cases in which an apparently trivial circumstance combines with the actually operative event or occurs at a time of peculiar susceptibility to stimulation and in this way attains the dignity of a trauma which it would not otherwise have possessed but which thenceforward persists.

But the causal relation between the determining psychical trauma and the hysterical phenomenon is not of a kind implying that the trauma merely acts like an *agent provocateur* in releasing the symptom, which thereafter leads an independent existence. We must presume rather that the psychical trauma – or more precisely the memory of the trauma – acts like a foreign body which long after its entry must continue to be regarded as an agent that is still at work; and we find the evidence for this in a highly remarkable phenomenon which at the same time lends an important *practical* interest to our findings.

For we found, to our great surprise at first, that *each individual hysterical symptom immediately and permanently disappeared when we had succeeded in bringing clearly to light the memory of the event by which it was provoked and in arousing its accompanying affect, and when the patient had described that event in the greatest possible detail and had put the affect into words*. Recollection without affect almost invariably produces no result. The psychical process which originally took place must be repeated as vividly as possible; it must be brought back to its *status nascendi* and then given verbal utterance. Where what we are
[7] dealing with are phenomena involving stimuli (spasms, neuralgias and hallucinations) these reappear once again with the fullest intensity and then vanish forever. Failures of function, such as paralyses and anaesthesias, vanish in the same way, though, of course, without the temporary intensification being discernible.[1]

It is plausible to suppose that it is a question here of unconscious suggestion: the patient expects to be relieved of his sufferings by this

1 The possibility of a therapeutic procedure of this kind has been clearly recognized by Delboeuf and Binet, as is shown by the following quotations: 'On s'expliquerait dès lors comment le magnétiseur aide à la guérison. Il remet le sujet dans l'état où le mal s'est manifesté et combat par la parole le même mal, mais renaissant.' ['We can now explain how the hypnotist promotes cure. He puts the subject back into the state in which his trouble first appeared and uses words to combat that trouble, as it now makes a fresh emergence.'] (Delboeuf, 1889.) – '. . . peut-être verra-t-on qu'en reportant le malade par un artifice mental au moment même où le symptôme a apparu pour la première fois, on rend ce malade plus docile à une suggestion curative.' ['. . . we shall perhaps find that by taking the patient back by means of a mental artifice to the very moment at which the symptom first appeared, we may make him more susceptible to a therapeutic suggestion.'] (Binet, 1892, 243.) – In Janet's interesting study on mental automatism (1889), there is an account of the cure of a hysterical girl by a method analogous to ours.

procedure, and it is this expectation, and not the verbal utterance, which is the operative factor. This, however, is not so. The first case of this kind that came under observation dates back to the year 1881, that is to say to the 'presuggestion' era. A highly complicated case of hysteria was analysed in this way, and the symptoms, which sprang from separate causes, were separately removed. This observation was made possible by spontaneous autohypnoses on the part of the patient, and came as a great surprise to the observer.[1]

We may reverse the dictum '*cessante causa cessat effectus*' ['when the cause ceases the effect ceases'] and conclude from these observations that the determining process continues to operate in some way or other for years – not indirectly, through a chain of intermediate causal links, but as a *directly* releasing cause – just as a psychical pain that is remembered in waking consciousness still provokes a lachrymal secretion long after the event. *Hysterics suffer mainly from reminiscences*.[2]

II

At first sight it seems extraordinary that events experienced so long ago should continue to operate so intensely – that their recollection should not be liable to the wearing-away process to which, after all, we see all our memories succumb. The following considerations may perhaps make this a little more intelligible. [8]

The fading of a memory or the losing of its affect depends on various factors. The most important of these is *whether there has been an energetic reaction to the event that provokes an affect*. By 'reaction' we here understand the whole class of voluntary and involuntary reflexes – from tears to acts of revenge – in which, as experience shows us, the affects are discharged [*entladen*][T]. If this reaction takes place to a sufficient amount a large part of the affect disappears as a result. Linguistic usage bears witness to this fact of daily observation by such phrases as 'to cry oneself out' ['*sich ausweinen*'], and to 'blow off steam' ['*sich austoben*', literally 'to rage oneself out']. If the reaction is suppressed, the affect remains attached to the memory. An injury that has been repaid, even if only in words, is recollected quite differently from one that has had to be

1 [The first event of this kind is reported on p. 30 below.]

2 In this preliminary communication it is not possible for us to distinguish what is new in it from what has been said by other authors such as Moebius and Strümpell who have held similar views on hysteria to ours. We have found the nearest approach to what we have to say on the theoretical and therapeutic sides of the question in some remarks, published from time to time, by Benedikt. These we shall deal with elsewhere. [See p. 187 *n*. below. Cf. Andersson (1962), 114 *n*. 3.]

accepted. Language recognizes this distinction, too, in its psychical and bodily consequences; it very characteristically describes an injury that has been suffered in silence as 'a mortification' ['*Kränkung*', literally 'making ill']. – The injured person's reaction to the trauma only exercises a completely 'cathartic' effect if it is an *adequate* reaction – as, for instance, revenge. But language serves as a substitute for action [*die Tat*][t]; by its help, an affect can be 'abreacted' almost as effectively.[1] In other cases speaking is itself the adequate reflex, when, for instance, it is a lamentation or giving utterance to a tormenting secret, e.g. a confession. If there is no such reaction, whether in deeds or words, or in the mildest cases in tears, any recollection of the event retains its affective tone to begin with.

[9] 'Abreaction', however, is not the only method of dealing with the situation that is open to a normal person who has experienced a psychical trauma. A memory of such a trauma, even if it has not been abreacted, enters the great complex of associations [*Assoziation*][T], it comes alongside other experiences, which may contradict it, and is subjected to rectification by other ideas [*Vorstellungen*]. After an accident, for instance, the memory of the danger and the (mitigated) repetition of the fright becomes associated with the memory of what happened afterwards – rescue and the consciousness of present safety. Again, a person's memory of a humiliation is corrected by his putting the facts right, by considering his own worth, etc. In this way a normal person is able to bring about the disappearance of the accompanying affect through the process of association.

To this we must add the general effacement of impressions, the fading of memories which we name 'forgetting' and which wears away those ideas in particular that are no longer affectively operative.

Our observations have shown, on the other hand, that the memories which have become the determinants of hysterical phenomena persist for a long time with astonishing freshness and with the whole of their affective colouring. We must, however, mention another remarkable fact, which we shall later be able to turn to account, namely, that these memories, unlike other memories of their past lives, are not at the patients' disposal. On the contrary, *these experiences are completely absent from the patients' memory when they are in a normal psychical state, or are only present in a highly summary form*. Not until they have been questioned under hypnosis do these memories emerge with the undiminished vividness of a recent event.

1 ['Catharsis' and 'abreaction' made their first published appearance in this passage. Freud had used the term 'abreaction' previously (June 28, 1892), in a letter to Fliess referring to the present paper (Freud, 1950*a*, Letter 9).]

Thus, for six whole months, one of our patients reproduced under hypnosis with hallucinatory vividness everything that had excited her on the same day of the previous year (during an attack of acute hysteria). A diary kept by her mother without her knowledge proved the completeness of the reproduction [p. 30 below]. Another patient, partly under hypnosis and partly during spontaneous attacks, relived with hallucinatory clarity all the events of a hysterical psychosis which she had passed through ten years earlier and which she had for the most part forgotten till the moment at which it re-emerged. Moreover, certain memories of aetiological importance which dated back from fifteen to twenty-five [10]
years were found to be astonishingly intact and to possess remarkable sensory force, and when they returned they acted with all the affective strength of new experiences [pp. 158–60 below].

This can only be explained on the view that these memories constitute an exception in their relation to all the wearing-away processes which we have discussed above. *It appears, that is to say, that these memories correspond to traumas that have not been sufficiently abreacted*; and if we enter more closely into the reasons which have prevented this, we find at least two sets of conditions under which the reaction to the trauma fails to occur.

In the first group are those cases in which the patients have not reacted to a psychical trauma because the nature of the trauma excluded a reaction, as in the case of the apparently irreparable loss of a loved person or because social circumstances made a reaction impossible or because it was a question of things which the patient wished to forget, and therefore intentionally repressed[1] from his conscious thought and inhibited [*hemmte*][T] and suppressed. It is precisely distressing things of this kind *Hemmung*

1 [This is the first appearance of the term 'repressed' ('*verdrängte*') in what was to be its psychoanalytic sense. The concept, though not the term, had already been used by Breuer & Freud in the joint, posthumously published draft (1940*d*), which was written in November, 1892, only about a month before the present paper. Freud's own first published use of the word was in the first section of his first paper on defence neurosis (1894*a*); and it occurs several times in his later contributions to the present volume (e.g. on p. 102 below). At this period 'repression' was used as an equivalent to 'defence' ('*Abwehr*'), as is shown, for instance, in the joint Preface to the first edition (p. xxvii above). The word 'defence' does not occur in the 'Preliminary Communication', however. It also first appeared in Section I of Freud's first paper on 'The Neuropsychoses of Defence' (1894*a*), and, like 'repression', is freely used by him in the later parts of the *Studies* (e.g. on p. 130). Breuer uses both terms in his theoretical chapter (e.g. on pp. 191 and 219). – On some of its earlier appearances the term 'repressed' is accompanied (as here) by the adverb 'intentionally' ('*absichtlich*') or by 'deliberately' ('*willkürlich*'). This is expanded by Freud in one place (1894*a*), where he states that the act of repression is 'initiated by an effort of will whose motive can be specified' (*RSE*, **3**, 44). Thus the word 'intentionally' merely indicates the existence of a motive and carries no implication of *conscious* intention. Indeed, a little later, at the beginning of his second paper on 'The Neuropsychoses of Defence' (1896*b*), *RSE*, **3**, 173, Freud explicitly describes the psychical mechanism of defence as 'unconscious'. – Some remarks on the origin of the concept of repression can be found in the Editors' Introduction, p. xxii above.]

[11] that, under hypnosis, we find are the basis of hysterical phenomena (e.g. hysterical deliria in saints and nuns, continent women and well-brought-up children).

The second group of conditions are determined, not by the content of the memories but by the psychical states in which the patient received the experiences in question. For we find, under hypnosis, among the causes of hysterical symptoms ideas which are not in themselves significant, but whose persistence is due to the fact that they originated during the prevalence of severely paralysing affects, such as fright, or during positively abnormal psychical states, such as the semi-hypnotic twilight state of daydreaming, autohypnoses, and so on. In such cases it is the nature of the states which makes a reaction to the event impossible.

Both kinds of conditions may, of course, be simultaneously present, and this, in fact, often occurs. It is so when a trauma which is operative in itself takes place while a severely paralysing affect prevails or during a modified state of consciousness. But it also seems to be true that in many people a psychical trauma *produces* one of these abnormal states, which, in turn, makes reaction impossible.

Both of these groups of conditions, however, have in common the fact that the psychical traumas which have not been disposed of by reaction cannot be disposed of either by being worked over by means of association. In the first group the patient is determined to forget the distressing experiences and accordingly excludes them so far as possible from association; while in the second group the associative working over fails to occur because there is no extensive associative connection between the normal state of consciousness and the pathological ones in which the ideas made their appearance. We shall have occasion immediately to enter further into this matter.

It may therefore be said that the ideas which have become pathological have persisted with such freshness and affective strength because they *Versagung* *have been denied* [*versagt*]^{T} *the normal wearing-away processes by means of abreaction and reproduction in states of uninhibited association*.

III

We have stated the conditions which, as our experience shows, are [12] responsible for the development of hysterical phenomena from psychical traumas. In so doing, we have already been obliged to speak of abnormal states of consciousness in which these pathogenic ideas arise, and to emphasize the fact that the recollection of the operative psychical

trauma is not to be found in the patient's normal memory but in his memory when he is hypnotized. The longer we have been occupied with these phenomena the more we have become convinced that *the splitting of consciousness which is so striking in the well-known classical cases under the form of* 'double conscience'[1] *is present to a rudimentary degree in every hysteria, and that a tendency to such a dissociation, and with it the emergence of abnormal states of consciousness (which we shall bring together under the term 'hypnoid') is the basic phenomenon of this neurosis*. In these views we concur with Binet and the two Janets,[2] though we have had no experience of the remarkable findings they have made on anaesthetic patients.

We should like to balance the familiar thesis that hypnosis is an artificial hysteria by another – the basis and *sine qua non* of hysteria is the existence of hypnoid states. These hypnoid states share with one another and with hypnosis, however much they may differ in other respects, one common feature: the ideas which emerge in them are very intense but are cut off from associative communication with the rest of the content of consciousness. Associations may take place between these hypnoid states, and their ideational content can in this way reach a more or less high degree of psychical organization. Moreover, the nature of these states and the extent to which they are cut off from the remaining conscious processes must be supposed to vary just as happens in hypnosis, which ranges from a light drowsiness to somnambulism, from complete recollection to total amnesia.

If hypnoid states of this kind are already present before the onset of the manifest illness, they provide the soil in which the affect plants the pathogenic memory with its consequent somatic phenomena. This corresponds to *dispositional* hysteria. We have found, however, that a severe trauma (such as occurs in a traumatic neurosis) or a laborious suppression (as of a sexual affect, for instance) can bring about a splitting off of groups of ideas even in people who are in other respects unaffected; and this would be the mechanism of *psychically acquired* hysteria. [13] Between the extremes of these two forms we must assume the existence of a series of cases within which the liability to dissociation in the subject and the affective magnitude of the trauma vary inversely.

We have nothing new to say on the question of the origin of these dispositional hypnoid states. They often, it would seem, grow out of the daydreams which are so common even in healthy people and to which

1 [The French term ('dual consciousness').]

2 [Pierre and Jules.]

needlework and similar occupations render women especially prone. Why it is that the 'pathological associations' brought about in these states are so stable and why they have so much more influence on somatic processes than ideas are usually found to do – these questions coincide with the general problem of the effectiveness of hypnotic suggestions. Our observations contribute nothing fresh on this subject. But they throw a light on the contradiction between the dictum 'hysteria is a psychosis' and the fact that among hysterics may be found people of the clearest intellect, strongest will, greatest character and highest critical power. This characterization holds good of their waking thoughts; but in their hypnoid states they are insane, as we all are in dreams. Whereas, however, our dream psychoses have no effect upon our waking state, the products of hypnoid states intrude into waking life in the form of hysterical symptoms.[1]

IV

What we have asserted of chronic hysterical symptoms can be applied almost completely to hysterical *attacks*. Charcot, as is well known, has given us a schematic description of the 'major' hysterical attack, according to which four phases can be distinguished in a complete attack: (1) the epileptoid phase, (2) the phase of large movements, (3) the phase of '*attitudes passionnelles*' (the hallucinatory phase), and (4) the phase of terminal delirium. Charcot derives all those forms of hysterical attack which are in practice met with more often than the complete '*grande attaque*', from the abbreviation or prolongation, absence or isolation of these four distinct phases.[2]

[14] Our attempted explanation takes its start from the third of these phases, that of the '*attitudes passionnelles*'. Where this is present in a well-marked form, it exhibits the hallucinatory reproduction of a memory which was of importance in bringing about the onset of the hysteria – the memory either of a single major trauma (which we find *par excellence* in what is called traumatic hysteria) or of a series of interconnected part-traumas (such as underlie common hysteria). Or, lastly, the attack may revive the events which have become emphasized owing to their *coinciding* with a moment of special disposition to trauma.

1 [A preliminary sketch of this section of the paper has survived in a posthumously published memorandum (Freud, 1941*b* [1892]), which is headed 'III', *RSE*, **1**, 177 f.]

2 [Cf. Charcot, 1887, 261.]

There are also attacks, however, which appear to consist exclusively of motor phenomena and in which the phase of *attitudes passionnelles* is absent. If one can succeed in getting into *rapport* with the patient during an attack such as this of generalized clonic spasms or cataleptic rigidity, or during an *attaque de sommeil* [attack of sleep] – or if, better still, one can succeed in provoking the attack under hypnosis – one finds that here, too, there is an underlying memory of the psychical trauma or series of traumas, which usually comes to our notice in a hallucinatory phase.

Thus, a little girl suffered for years from attacks of general convulsions which could well be, and indeed were, regarded as epileptic. She was hypnotized with a view to a differential diagnosis, and promptly had one of her attacks. She was asked what she was seeing and replied 'The dog! The dog's coming!'; and in fact it turned out that she had had the first of her attacks after being chased by a savage dog. The success of the treatment confirmed the choice of diagnosis.

Again, an employee who had become a hysteric as a result of being ill-treated by his superior, suffered from attacks in which he collapsed and fell into a frenzy of rage, but without uttering a word or giving any sign of a hallucination. It was possible to provoke an attack under hypnosis, and the patient then revealed that he was living through the scene in which his employer had abused him in the street and hit him with a stick. A few days later the patient came back and complained of having had another attack of the same kind. On this occasion it turned out under hypnosis that he had been reliving the scene to which the actual onset of the illness was related: the scene in the law court when he failed to obtain satisfaction for his maltreatment.

In all other respects, too, the memories which emerge, or can be aroused, in hysterical attacks correspond to the precipitating causes which we have found at the root of *chronic* hysterical symptoms. Like these latter causes, the memories underlying hysterical attacks relate to psychical traumas which have not been disposed of by abreaction or by associative thought activity. Like them, they are, whether completely or in essential elements, out of reach of the memory of normal consciousness and are found to belong to the ideational content of hypnoid states of consciousness with restricted association. Finally, too, the therapeutic test can be applied to them. Our observations have often taught us that a memory of this kind which had hitherto provoked attacks ceases to be able to do so after the process of reaction and associative correction have been applied to it under hypnosis. [15]

The motor phenomena of hysterical attacks can be interpreted partly as universal forms of reaction appropriate to the affect accompanying the memory (such as kicking about and waving the arms and legs, which even young babies do), partly as a direct expression of these memories; but in part, like the hysterical stigmata[1] found among the chronic symptoms, they cannot be explained in this way.

Hysterical attacks, furthermore, appear in a specially interesting light if we bear in mind a theory that we have mentioned above, namely, that in hysteria groups of ideas originating in hypnoid states are present and that these are cut off from associative connection with the other ideas, but can be associated among themselves, and thus form the more or less highly organized rudiment of a second consciousness, a *condition seconde*. If this is so, a chronic hysterical symptom will correspond to the intrusion of this second state into the somatic innervation which is as a rule under the control of normal consciousness. A hysterical attack, on the other hand, is evidence of a higher organization of this second state. When the attack makes its first appearance, it indicates a moment at which this hypnoid consciousness has obtained control of the subject's whole existence – it points, that is, to an acute hysteria; when it occurs on subsequent occasions and contains a memory, it points to a return of
[16] that moment. Charcot has already suggested that hysterical attacks are a rudimentary form of a *condition seconde*. During the attack, control over the whole of the somatic innervation passes over to the hypnoid consciousness. Normal consciousness, as well-known observations show, is not always entirely repressed. It may even be aware of the motor phenomena of the attack, while the accompanying psychical events are outside its knowledge.

The typical course of a severe case of hysteria is, as we know, as follows. To begin with, an ideational content is formed during hypnoid states; when this has increased to a sufficient extent, it gains control, during a period of 'acute hysteria', of the somatic innervation and of the patient's whole existence, and creates chronic symptoms and attacks; after this it clears up, apart from certain residues. If the normal personality can regain control, what is left over from the hypnoid ideational content recurs in hysterical attacks and puts the subject back from time to time into similar states, which are themselves once more open to influence and susceptible to traumas. A state of equilibrium, as it were, may then be established between the two psychical groups which are combined in the same

1 ['The permanent symptoms of hysteria.' (Charcot, 1887, 255.) Stigmata are discussed by Breuer below, p. 218.]

person: hysterical attacks and normal life proceed side by side without interfering with each other. An attack will occur spontaneously, just as memories do in normal people; it is, however, possible to provoke one, just as any memory can be aroused in accordance with the laws of association. It can be provoked either by stimulation of a hysterogenic zone[1] or by a new experience which sets it going owing to a similarity with the pathogenic experience. We hope to be able to show that these two kinds of determinant, though they appear to be so unlike, do not differ in essentials, but that in both a hyperaesthetic memory is touched on.

In other cases this equilibrium is very unstable. The attack makes its appearance as a manifestation of the residue of the hypnoid consciousness whenever the normal personality is exhausted and incapacitated. The possibility cannot be dismissed that here the attack may have been divested of its original meaning and may be recurring as a motor reaction without any content.

It must be left to further investigation to discover what it is that determines whether a hysterical personality manifests itself in attacks, in chronic symptoms or in a mixture of the two.[2] [17]

V

It will now be understood how it is that the psychotherapeutic procedure which we have described in these pages has a curative effect. *It brings to an end the operative force of the idea which was not abreacted in the first instance, by allowing its strangulated affect to find a way out through speech; and it subjects it to associative correction by introducing it into normal consciousness (under light hypnosis) or by removing it through the physician's suggestion, as is done in somnambulism accompanied by amnesia*.

In our opinion the therapeutic advantages of this procedure are considerable. It is of course true that we do not cure hysteria insofar as it is a matter of disposition. We can do nothing against the recurrence of hypnoid states. Moreover, during the productive stage of an acute hysteria our procedure cannot prevent the phenomena which have been so laboriously removed from being at once replaced by fresh ones. But once this acute stage is past, any residues which may be left in the form of chronic symptoms or attacks are often removed, and permanently so, by

1 [This is a term regularly used by Charcot, e.g. 1887, 85 ff.]

2 [A preliminary draft of this discussion on hysterical attacks, written in November, 1892, was published posthumously (Breuer & Freud, 1940*d*). The subject was dealt with much later by Freud in a paper on hysterical attacks (1909*a*), *RSE*, **9**, 201 ff.]

our method, because it is a radical one; in this respect it seems to us far superior in its efficacy to removal through direct suggestion, as it is practised today by psychotherapists.

If by uncovering the psychical mechanism of hysterical phenomena we have taken a step forward along the path first traced so successfully by Charcot with his explanation and artificial imitation of hysterotraumatic paralyses, we cannot conceal from ourselves that this has brought us nearer to an understanding only of the *mechanism* of hysterical symptoms and not of the internal causes of hysteria. We have done no more than touch upon the aetiology of hysteria and in fact have been able to throw light only on its acquired forms – on the bearing of accidental factors on the neurosis.

Vienna, December, 1892

CASE HISTORIES
(BREUER & FREUD)

II

CASE HISTORIES

(BREUER & FREUD)

CASE 1
FRÄULEIN ANNA O. (*BREUER*)

At the time of her falling ill (in 1880) Fraulein Anna O.[1] was twenty-one [21]
years old. She may be regarded as having had a moderately severe neuropathic heredity, since some psychoses had occurred among her more distant relatives. Her parents were normal in this respect. She herself had hitherto been consistently healthy and had shown no signs of neurosis during her period of growth.[2] She was markedly intelligent, with an astonishingly quick grasp of things and penetrating intuition. She possessed a powerful intellect which would have been capable of digesting solid mental pabulum and which stood in need of it – though without receiving it after she had left school. She had great poetic and imaginative gifts, which were under the control of a sharp and critical common sense. Owing to this latter quality she was *completely unsuggestible*; she was only influenced by arguments, never by mere assertions. Her willpower was energetic, tenacious and persistent; sometimes it reached the pitch of an obstinacy which only gave way out of kindness and regard for other people.

One of her essential character traits was sympathetic kindness.[3] Even during her illness she herself was greatly assisted by being able to look after a number of poor, sick people, for she was thus able to satisfy a powerful drive [*Trieb*][T]. Her states of feeling always tended to a slight exaggeration, alike of cheerfulness and gloom; hence she was sometimes subject to moods. The element of sexuality was astonishingly undeveloped in her.[4] The patient, whose life became known to me to

1 [The life of 'Anna O.' has been thoroughly researched. See in particular Ellenberger (1970, 1972), Hirschmüller (1978*b*) and Jensen (1984).]

2 [She is said to have been 'overprotected' as two of her three siblings died young and she was the only surviving daughter.]

3 [After her illness, she became well known for her philanthropic and humanitarian work.]

4 [Freud discussed and quoted this sentence (not quite verbatim) in a footnote to the first of his *Three Essays on the Theory of Sexuality* (1905*d*), *RSE*, **7**, 146 *n.* 2, and in Chapter II of his autobiography (1925*d*), ibid., **20**, 19.]

[22] an extent to which one person's life is seldom known to another, had never been in love; and in all the enormous number of hallucinations[1] which occurred during her illness that element of mental life never emerged.

This girl, who was bubbling over with intellectual vitality, led an extremely monotonous existence in her puritanically minded family. She embellished her life in a manner which probably influenced her decisively in the direction of her illness, by indulging in systematic day-dreaming, which she described as her 'private theatre'. While everyone thought she was attending, she was living through fairy tales in her imagination; but she was always on the spot when she was spoken to, so that no-one was aware of it. She pursued this activity almost continuously while she was engaged on her household duties, which she discharged unexceptionably. I shall presently have to describe the way in which this habitual daydreaming while she was well passed over into illness without a break.

The course of the illness fell into several clearly separable phases:

(A) Latent incubation. From the middle of July, 1880, till about December 10. This phase of an illness is usually hidden from us; but in this case, owing to its peculiar character, it was completely accessible; and this in itself lends no small pathological interest to the history. I shall describe this phase presently.

(B) The manifest illness. A psychosis of a peculiar kind, paraphasia, a convergent squint, severe disturbances of vision, paralyses (in the form of contractures), complete in the right upper and both lower extremities, partial in the left upper extremity, paresis of the neck muscles. A gradual reduction of the contracture to the right-hand extremities. Some improvement, interrupted by a severe psychical trauma (the death of the patient's father) in April, after which there followed

(C) A period of persisting somnambulism, subsequently alternating with more normal states. A number of chronic symptoms persisted till December, 1881.

(D) Gradual cessation of the pathological states and symptoms up to June, 1882.[2]

In July, 1880, the patient's father, of whom she was passionately fond,
[23] fell ill of a peripleuritic abscess which failed to clear up and to which he succumbed in April, 1881. During the first months of the illness Anna

1 [Diverse attempts have been made at retrospective rediagnosis of all the cases in these *Studies*. See Hirschmüller (1978*b*) for a discussion of the pitfalls involved in such 'paleodiagnostics'.]

2 [See footnote, p. 30 f. below.]

devoted her whole energy to nursing her father, and no-one was much surprised when by degrees her own health greatly deteriorated. No-one, perhaps not even the patient herself, knew what was happening to her; but eventually the state of weakness, anaemia and distaste for food became so bad that to her great sorrow she was no longer allowed to continue nursing the patient. The immediate cause of this was a very severe cough, on account of which I examined her for the first time. It was a typical *tussis nervosa*. She soon began to display a marked craving for rest during the afternoon, followed in the evening by a sleeplike state and afterwards a highly excited condition.

At the beginning of December a convergent squint appeared. An ophthalmic surgeon explained this (mistakenly) as being due to paresis of one abducens. On December 11 the patient took to her bed and remained there until April 1.

There developed in rapid succession a series of severe disturbances which were *apparently* quite new: left-sided occipital headache; convergent squint (diplopia), markedly increased by excitement; complaints that the walls of the room seemed to be falling over (affection of the obliquus); disturbances of vision which it was hard to analyse; paresis of the muscles of the front of the neck, so that finally the patient could only move her head by pressing it backwards between her raised shoulders and moving her whole back; contracture and anaesthesia of the right upper, and, after a time, of the right lower extremity. The latter was fully extended, adducted and rotated inwards. Later the same symptom appeared in the left lower extremity and finally in the left arm, of which, however, the fingers to some extent retained the power of movement. So, too, there was no complete rigidity in the shoulder joints. The contracture reached its maximum in the muscles of the upper arms. In the same way, the region of the elbows turned out to be the most affected by anaesthesia when, at a later stage, it became possible to make a more careful test of this. At the beginning of the illness the anaesthesia could not be efficiently tested, owing to the patient's resistance arising from feelings of anxiety.

It was while the patient was in this condition that I undertook her treatment, and I at once recognized the seriousness of the psychical [24]
disturbance with which I had to deal. Two entirely distinct states of consciousness were present which alternated very frequently and without warning and which became more and more differentiated in the course of the illness. In one of these states she recognized her surroundings; she was melancholy and anxious, but relatively normal. In

the other state she hallucinated and was 'naughty' – that is to say, she was abusive, used to throw the cushions at people, so far as the contractures at various times allowed, tore buttons off her bedclothes and linen with those of her fingers which she could move, and so on. At this stage of her illness if something had been moved in the room or someone had entered or left it [during her other state of consciousness] she would complain of having 'lost' some time and would remark upon the gap in her train of conscious thoughts. Since those about her tried to deny this and to soothe her when she complained that she was going mad, she would, after throwing the pillows about, accuse people of doing things to her and leaving her in a muddle, etc.

These '*absences*'[1] had already been observed before she took to her bed; she used then to stop in the middle of a sentence, repeat her last words and after a short pause go on talking. These interruptions gradually increased till they reached the dimensions that have just been described; and during the climax of the illness, when the contractures had extended to the left side of her body, it was only for a short time during the day that she was to any degree normal. But the disturbances invaded even her moments of relatively clear consciousness. There were extremely rapid changes of mood leading to excessive but quite temporary high spirits, and at other times severe anxiety, stubborn opposition to every therapeutic effort and frightening hallucinations of black snakes, which was how she saw her hair, ribbons and similar things. At the same time she kept on telling herself not to be so silly: what she was seeing was really only her hair, etc. At moments when her mind was quite clear she would complain of the profound darkness in her head, of not being able to think, of becoming blind and deaf, of having two selves, a real one and an evil one which forced her to behave badly, and so on.

In the afternoons she would fall into a somnolent state which lasted
[25] till about an hour after sunset. She would then wake up and complain that something was tormenting her – or rather, she would keep repeating in the impersonal form 'tormenting, tormenting'. For alongside of the development of the contractures there appeared a deep-going functional disorganization of her speech. It first became noticeable that she was at a loss to find words, and this difficulty gradually increased. Later she lost her command of grammar and syntax; she no longer conjugated verbs, and eventually she used only infinitives, for the most part incorrectly formed from weak past participles; and she omitted both the

1 [The French term.]

definite and indefinite article. In the process of time she became almost completely deprived of words. She put them together laboriously out of four or five languages and became almost unintelligible. When she tried to write (until her contractures entirely prevented her doing so) she employed the same jargon. For two weeks she became completely dumb and in spite of making great and continuous efforts to speak she was unable to say a syllable. And now for the first time the psychical mechanism of the disorder became clear. As I knew, she had felt very much offended over something and had determined not to speak about it. When I guessed this and obliged her to talk about it, the inhibition, which had made any other kind of utterance impossible as well, disappeared.

This change coincided with a return of the power of movement to the extremities of the left side of her body, in March, 1881. Her paraphasia receded; but thenceforward she spoke only in English – apparently, however, without knowing that she was doing so. She had disputes with her nurse who was, of course, unable to understand her. It was only some months later that I was able to convince her that she was talking English. Nevertheless, she herself could still understand the people about her who talked German. Only in moments of extreme anxiety did her power of speech desert her entirely, or else she would use a mixture of all sorts of languages. At times when she was at her very best and most free, she talked French and Italian. There was complete amnesia between these times and those at which she talked English. At this point, too, her squint began to diminish and made its appearance only at moments of great excitement. She was once again able to support her head. On the first of April she got up for the first time.

On the fifth of April her adored father died. During her illness she [26]
had seen him very rarely and for short periods. This was the most severe psychical trauma that she could possibly have experienced.[1] A violent outburst of excitement was succeeded by profound stupor which lasted about two days and from which she emerged in a greatly changed state. At first she was far quieter and her feelings of anxiety were much diminished. The contracture of her right arm and leg persisted as well as their anaesthesia, though this was not deep. There was a high degree of

1 [A case report prepared by Breuer in 1882 for the Bellevue sanatorium in Kreuzlingen reveals that the trauma was compounded by the fact that she had not seen her father for the previous two months, that the seriousness of his condition had been kept from her, and that she had therefore been deprived of a final contact with him. The 1882 report, which differs in some respects from this one, is published in Hirschmüller (1978*b*). The more significant differences, as well as other important details brought to light by Hirschmüller, are annotated below.]

restriction of the field of vision: in a bunch of flowers which gave her much pleasure she could only see one flower at a time. She complained of not being able to recognize people. Normally, she said, she had been able to recognize faces without having to make any deliberate effort; now she was obliged to do laborious 'recognizing work'[1] and had to say to herself 'this person's nose is such-and-such, his hair is such-and-such, so he must be so-and-so'. All the people she saw seemed like wax figures without any connection with her. She found the presence of some of her close relatives very distressing and this negative attitude grew continually stronger. If someone whom she was ordinarily pleased to see came into the room, she would recognize him and would be aware of things for a short time, but would soon sink back into her own broodings and her visitor was blotted out. I was the only person whom she always recognized when I came in; so long as I was talking to her she was always in contact with things and lively, except for the sudden interruptions caused by one of her hallucinatory '*absences*'.

She now spoke only English and could not understand what was said to her in German. Those about her were obliged to talk to her in English; even the nurse learnt to make herself to some extent understood in this way. She was, however, able to read French and Italian. If she had to read one of these aloud, what she produced, with extraordinary fluency, was an admirable extempore English translation.

She began writing again, but in a peculiar fashion. She wrote with her left hand, the less stiff one, and she used Roman printed letters, copying the alphabet from her edition of Shakespeare.

She had eaten extremely little previously, but now she refused nour-
[27] ishment altogether. However, she allowed me to feed her, so that she very soon began to take more food. But she never consented to eat bread. After her meal she invariably rinsed out her mouth and even did so if, for any reason, she had not eaten anything – which shows how absent-minded she was about such things.

Her somnolent states in the afternoon and her deep sleep after sunset persisted. If, after this, she had talked herself out (I shall have to explain what is meant by this later) she was clear in mind, calm and cheerful.

This comparatively tolerable state did not last long. Some ten days after her father's death a consultant[2] was brought in, whom, like all strangers, she completely ignored while I demonstrated all her peculiarities to him. 'That's like an examination,'[3] she said, laughing,

1 [In English in the original.]

2 [This was Richard Krafft-Ebing, the eminent psychiatrist.]

3 [In English in the original.]

when I got her to read a French text aloud in English. The other physician intervened in the conversation and tried to attract her attention, but in vain. It was a genuine 'negative hallucination' of the kind which has since so often been produced experimentally. In the end he succeeded in breaking through it by blowing smoke in her face. She suddenly saw a stranger before her, rushed to the door to take away the key and fell unconscious to the ground. There followed a short fit of anger and then a severe attack of anxiety which I had great difficulty in calming down. Unluckily I had to leave Vienna that evening, and when I came back several days later I found the patient much worse. She had gone entirely without food the whole time, was full of anxiety and her hallucinatory *absences* were filled with terrifying figures, death's heads and skeletons. Since she acted these things through as though she was experiencing them and in part put them into words, the people around her became aware to a great extent of the content of these hallucinations.

The regular order of things was: the somnolent state in the afternoon, followed after sunset by the deep hypnosis for which she invented the technical name of 'clouds'.[1] If during this she was able to narrate the hallucinations she had had in the course of the day, she would wake up clear in mind, calm and cheerful. She would sit down to work and write or draw far into the night quite rationally. At about four she would go to bed. Next day the whole series of events would be repeated. It was a truly remarkable contrast: in the daytime the irresponsible patient pursued by hallucinations, and at night the girl with her mind completely clear. [28]

In spite of her euphoria at night, her psychical condition deteriorated steadily. Strong suicidal impulses appeared which made it seem inadvisable for her to continue living on the third floor. Against her will, therefore, she was transferred to a country house in the neighbourhood of Vienna (on June 7, 1881).[2] I had never threatened her with this removal from her home, which she regarded with horror, but she herself had, without saying so, expected and dreaded it. This event made it clear once more how much the affect of anxiety dominated her psychical disorder. Just as after her father's death a calmer condition had set in, so now, when what she feared had actually taken place, she once more became calmer. Nevertheless, the move was immediately followed by

1 [In English in the original.]

2 [This was Inzersdorf. While there she was supervised by the sanatorium doctors and nursing staff but still treated by Breuer himself, though no longer daily.]

three days and nights completely without sleep or nourishment, by numerous attempts at suicide (though, so long as she was in a garden, these were not dangerous), by smashing windows and so on, and by hallucinations unaccompanied by *absences* – which she was able to distinguish easily from her other hallucinations. After this she grew quieter, let the nurse feed her and even took chloral at night.

Before continuing my account of the case, I must go back once more and describe one of its peculiarities which I have hitherto mentioned only in passing. I have already said that throughout the illness up to this point the patient fell into a somnolent state every afternoon and that after sunset this period passed into a deeper sleep – 'clouds'. (It seems plausible to attribute this regular sequence of events merely to her experience while she was nursing her father, which she had had to do for several months. During the nights she had watched by the patient's bedside or had been awake anxiously listening till the morning; in the afternoons she had lain down for a short rest, as is the usual habit of nurses. This pattern of waking at night and sleeping in the afternoons seems to have been carried over into her own illness and to have persisted long after the sleep had been replaced by a hypnotic state.) After the deep sleep had lasted about an hour she grew restless, tossed to and fro and kept repeating 'tormenting, tormenting', with her eyes shut all the time. It was also noticed how, during her *absences* in daytime, she
[29] was obviously creating some situation or episode to which she gave a clue with a few muttered words. It happened then – to begin with accidentally but later intentionally – that someone near her repeated one of these phrases of hers while she was complaining about the 'tormenting'. She at once joined in and began to paint some situation or tell some story, hesitatingly at first and in her paraphasic jargon; but the longer she went on the more fluent she became, till at last she was speaking quite correct German. (This applies to the early period before she began talking English only [p. 23 above].) The stories were always sad and some of them very charming, in the style of Hans Andersen's *Picture-book without Pictures*, and, indeed, they were probably constructed on that model.[1] As a rule their starting point or central situation was of a girl anxiously sitting by a sick-bed. But she also built up her stories on quite other topics. – A few moments after she had finished her narrative she would wake up, obviously calmed down, or, as she called it,

1 [In the later 1880s she published anonymously a collection of five short stories entitled *Kleine Geschichten für Kinder* ('Little Stories for Children'). The exact date of publication is uncertain. A second collection of stories, *In der Trödelbude* ('In the Junk Shop'), appeared in 1890, under the pseudonym P. Berthold.]

'*gehäglich*'.[1] During the night she would again become restless, and in the morning, after a couple of hours' sleep, she was visibly involved in some other set of ideas. – If for any reason she was unable to tell me the story during her evening hypnosis she failed to calm down afterwards, and on the following day she had to tell me *two* stories in order for this to happen.

The essential features of this phenomenon – the mounting up and intensification of her *absences* into her autohypnosis in the evening, the effect of the products of her imagination as psychical stimuli and the easing and removal of her state of stimulation when she gave utterance to them in her hypnosis – remained constant throughout the whole eighteen months during which she was under observation.

The stories naturally became still more tragic after her father's death. It was not, however, until the deterioration of her mental condition, which followed when her state of somnambulism was forcibly broken into in the way already described, that her evening narratives ceased to have the character of more or less freely created poetical compositions and changed into a string of frightful and terrifying hallucinations. (It was already possible to arrive at these from the patient's behaviour during the day.) I have already [p. 25 above] described how completely her mind was relieved when, shaking with fear and horror, she had reproduced these frightful images and given verbal utterance to them. [30]

While she was in the country, when I was unable to pay her daily visits, the situation developed as follows. I used to visit her in the evening, when I knew I should find her in her hypnosis, and I then relieved her of the whole stock of imaginative products which she had accumulated since my last visit. It was essential that this should be effected completely if good results were to follow. When this was done she became perfectly calm, and next day she would be agreeable, easy to manage, industrious and even cheerful; but on the second day she would be increasingly moody, contrary and unpleasant, and this would become still more marked on the third day. When she was like this it was not always easy to get her to talk, even in her hypnosis. She aptly described this procedure, speaking seriously, as a 'talking cure', while she referred to it jokingly as 'chimney-sweeping'.[2] She knew that after she had given utterance to her hallucinations she would lose all her obstinacy and what she described as her 'energy'; and when, after some comparatively long

1 [She used this made-up word instead of the regular German '*behaglich*', meaning 'comfortable'.]

2 [These two phrases are in English in the original.]

interval, she was in a bad temper, she would refuse to talk, and I was obliged to overcome her unwillingness by urging and pleading and using devices such as repeating a formula with which she was in the habit of introducing her stories. But she would never begin to talk until she had satisfied herself of my identity by carefully feeling my hands. On those nights on which she had not been calmed by verbal utterance it was necessary to fall back upon chloral. I had tried it on a few earlier occasions, but I was obliged to give her 5 grammes, and sleep was preceded by a state of intoxication which lasted for some hours. When I was present this state was euphoric, but in my absence it was highly disagreeable and characterized by anxiety as well as excitement. (It may be remarked incidentally that this severe state of intoxication made no difference to her contractures.) I had been able to avoid the use of narcotics, since the verbal utterance of her hallucinations calmed her even though it might not induce sleep; but when she was in the country the nights on which she had not obtained hypnotic relief were so unbearable that in
[31] spite of everything it was necessary to have recourse to chloral. But it became possible gradually to reduce the dose.[1]

The persisting somnambulism did not return. But on the other hand the alternation between two states of consciousness persisted. She used to hallucinate in the middle of a conversation, run off, start climbing up a tree, etc. If one caught hold of her, she would very quickly take up her interrupted sentence without knowing anything about what had happened in the interval. All these hallucinations, however, came up and were reported on in her hypnosis.

Her condition improved on the whole. She took nourishment without difficulty and allowed the nurse to feed her; except that she asked for bread but rejected it the moment it touched her lips. The paralytic contracture of the leg diminished greatly. There was also an improvement in her power of judgement and she became much attached to my friend Dr B., the physician who visited her. She derived much benefit from a Newfoundland dog which was given to her and of which she was passionately fond. On one occasion, though, her pet made an attack on a cat, and it was splendid to see the way in which the frail girl seized a whip in her left hand and beat off the huge beast with it to rescue his victim. Later, she looked after some poor, sick people, and this helped her greatly.

It was after I returned from a holiday trip which lasted several weeks

1 [The documentary evidence collected by Hirschmüller (1978*b*) shows that her reliance on chloral continued to wax and wane, and at one stage at least resulted in addiction. The same applies to morphine, which was used mainly for the treatment of the trigeminal neuralgia.]

that I received the most convincing evidence of the pathogenic and exciting effect brought about by the ideational complexes which were produced during her *absences*, or *condition seconde*, and of the fact that these complexes were disposed of by being given verbal expression during hypnosis. During this interval no 'talking cure' had been carried out, for it was impossible to persuade her to confide what she had to say to anyone but me – not even to Dr B. to whom she had in other respects become devoted. I found her in a wretched moral state, inert, unamenable, ill-tempered, even malicious. It became plain from her evening stories that her imaginative and poetic vein was drying up. What she reported was more and more concerned with her hallucinations and, for instance, the things that had annoyed her during the past days. These were clothed in imaginative shape, but were merely formulated in stereotyped images rather than elaborated into poetic productions. But the situation only became tolerable after I had arranged for the patient [32]
to be brought back to Vienna for a week and evening after evening made her tell me three to five stories. When I had accomplished this, everything that had accumulated during the weeks of my absence had been worked off. It was only now that the former rhythm was re-established: on the day after her giving verbal utterance to her phantasies she was amiable and cheerful, on the second day she was more irritable and less agreeable and on the third positively 'nasty'. Her moral state was a function of the time that had elapsed since her last utterance. This was because every one of the spontaneous products of her imagination and every event which had been assimilated by the pathological part of her mind persisted as a psychical stimulus until it had been narrated in her hypnosis, after which it completely ceased to operate.

When, in the autumn, the patient returned to Vienna (though to a different house from the one in which she had fallen ill), her condition was bearable, both physically and mentally; for very few of her experiences – in fact, only her more striking ones – were made into psychical stimuli in a pathological manner. I was hoping for a continuous and increasing improvement, provided that the permanent burdening of her mind with fresh stimuli could be prevented by her giving regular verbal expression to them. But to begin with I was disappointed. In December there was a marked deterioration of her psychical condition. She once more became excited, gloomy and irritable. She had no more 'really good days' even when it was impossible to detect anything that was remaining 'stuck' inside her. Towards the end of December, at Christmas time, she was particularly restless, and for a whole week in the

evenings she told me nothing new but only the imaginative products which she had elaborated day by day under the stress of great anxiety and emotion during the Christmas of 1880 [a year earlier]. When the series had been completed she was greatly relieved.

A year had now passed since she had been separated from her father and had taken to her bed, and from this time on her condition became clearer and was systematized in a very peculiar manner. Her alternating states of consciousness, which were characterized by the fact that, from morning onwards, her *absences* (that is to say, the emergence of her *condition seconde*) always became more frequent as the day advanced and took entire possession by the evening – these alternating states had
[33] differed from each other previously in that one (the first) was normal and the second alienated; now, however, they differed further in that in the first she lived, like the rest of us, in the winter of 1881–2, whereas in the second she lived in the winter of 1880–1, and had completely forgotten all the subsequent events. The one thing that nevertheless seemed to remain conscious most of the time was the fact that her father had died. She was carried back to the previous year with such intensity that in the new house she hallucinated her old room, so that when she wanted to go to the door she knocked up against the stove which stood in the same relation to the window as the door did in the old room. The changeover from one state to another occurred spontaneously but could also be very easily brought about by any sense impression which vividly recalled the previous year. One had only to hold up an orange before her eyes (oranges were what she had chiefly lived on during the first part of her illness) in order to carry her over from the year 1882 to the year 1881. But this transfer into the past did not take place in a general or indefinite manner; she lived through the previous winter day by day. I should only have been able to *suspect* that this was happening, had it not been that every evening during the hypnosis she talked through whatever it was that had excited her on the same day in 1881, and had it not been that a private diary kept by her mother in 1881 confirmed beyond a doubt the occurrence of the underlying events. This reliving of the previous year continued till the illness came to its final close in June, 1882.[1]

1 [This is misleading. At the end of the treatment various severe disturbances persisted and the patient was admitted to the Bellevue sanatorium in Kreuzlingen in late July, 1882. She was discharged ('condition improved') in October but required two further admissions to the Inzersdorf sanatorium between 1883 and 1887. The diagnosis was consistently 'hysteria'. However, the official examination of her mental state during her later Inzersdorf admissions also records 'somatic illness'. Breuer was aware of all these developments. Hirschmüller (1978*b*) concludes that Breuer believed she was suffering from an 'unknown cerebral disease' *complicated* by hysteria, and that only the latter condition (the part of her illness that he considered ideogenic and therefore accessible to psychotherapy) came to a close in June, 1882. (In apparent support of

It was interesting here, too, to observe the way in which these revived psychical stimuli belonging to her secondary state made their way over into her first, more normal one. It happened, for instance, that one morning the patient said to me laughingly that she had no idea what was the matter but she was angry with me. Thanks to the diary I knew what was happening; and, sure enough, this was gone through again in the evening hypnosis: I had annoyed the patient very much on the same evening in 1881. Or another time she told me there was something the matter with her eyes; she was seeing colours wrong. She knew she was wearing a brown dress but she saw it as a blue one. We soon found that she could distinguish all the colours of the visual test-sheets correctly and clearly, and that the disturbance only related to the dress material. The reason was that during the same period in 1881 she had been very [34] busy with a dressing-gown for her father, which was made with the same material as her present dress, but was blue instead of brown. Incidentally, it was often to be seen that these emergent memories showed their effect in advance; the disturbance of her normal state would occur earlier on, and the memory would only gradually be awakened in her *condition seconde*.[1]

Her evening hypnosis was thus heavily burdened, for we had to talk off not only her contemporary imaginative products but also the events and 'vexations'[2] of 1881. (Fortunately I had already relieved her at the time of the imaginative products of that year.) But in addition to all this the work that had to be done by the patient and her physician was immensely increased by a third group of separate disturbances which had to be disposed of in the same manner. These were the psychical events involved in the period of incubation of the illness between July and December, 1880; it was they that had produced the whole of the hysterical phenomena, and when they were brought to verbal utterance the symptoms disappeared.

When this happened for the first time – when, as a result of an accidental and spontaneous utterance of this kind, during the evening hypnosis, a disturbance which had persisted for a considerable time vanished – I was greatly surprised. It was in the summer during a period

this conclusion, see pp. 32 f., 46 and 166 ff. below.) Even so, it is evident that some hysterical symptoms persisted beyond June, 1882 (e.g. nocturnal aphasia for German). Cf. Breuer's own remark on p. 37 below, conceding that 'it was a considerable time before she regained her mental balance entirely'. It seems highly likely that the obscurity surrounding the outcome of the treatment was also attributable in part to Breuer's flight from the sexual transference (see p. 37 *n.* 1 below).]

1 [Cf. the similar phenomenon in the case of Frau Cäcilie, p. 62 *n.* below.]

2 [In English in the original.]

of extreme heat, and the patient was suffering very badly from thirst; for, without being able to account for it in any way, she suddenly found it impossible to drink. She would take up the glass of water she longed for, but as soon as it touched her lips she would push it away like someone suffering from hydrophobia. As she did this, she was obviously in an *absence* for a couple of seconds. She lived only on fruit, such as melons, etc., so as to lessen her tormenting thirst. This had lasted for some six weeks, when one day during hypnosis she grumbled about her English lady companion whom she did not care for, and went on to describe, with every sign of disgust, how she had once gone into that lady's room and how her little dog – horrid creature! – had drunk out of a glass there. The patient had said nothing, as she had wanted to be polite. After giving further energetic expression to the anger she had held back, she asked for something to drink, drank a large quantity of [35] water without any difficulty and woke from her hypnosis with the glass at her lips; and thereupon the disturbance vanished, never to return. A number of extremely obstinate whims were similarly removed after she had described the experiences which had given rise to them. She took a great step forward when the first of her chronic symptoms disappeared in the same way – the contracture of her right leg, which, it is true, had already diminished a great deal. These findings – that in the case of this patient the hysterical phenomena disappeared as soon as the event which had given rise to them was reproduced in her hypnosis – made it possible to arrive at a therapeutic technical procedure which left nothing to be desired in its logical consistency and systematic application. Each individual symptom in this complicated case was taken separately in hand; all the occasions on which it had appeared were described in reverse order, starting before the time when the patient became bedridden and going back to the event which had led to its first appearance. When this had been described the symptom was permanently removed.

In this way her paralytic contractures and anaesthesias, disorders of vision and hearing of every sort, neuralgias, coughing, tremors, etc., and finally her disturbances of speech were 'talked away'. Among the disorders of vision, the following, for instance, were disposed of separately: the convergent squint with diplopia; deviation of both eyes to the right, so that when her hand reached out for something it always went to the left of the object; restriction of the visual field; central amblyopia; macropsia; seeing a death's head instead of her father; inability to read. Only a few scattered phenomena (such, for instance, as the extension of the paralytic contractures to the left side of her body) which had

developed while she was confined to bed, were untouched by this process of analysis,[1] and it is probable, indeed, that they had in fact no immediate psychical cause [see footnote, p. 30 f. above].

It turned out to be quite impracticable to shorten the work by trying to elicit in her memory straight away the first provoking cause of her symptoms. She was unable to find it, grew confused, and things proceeded even more slowly than if she was allowed quietly and steadily to follow back the thread of memories on which she had embarked. Since the latter method, however, took too long in the evening hypnosis, [36] owing to her being over-strained and distraught by 'talking out' the two other sets of experiences – and owing, too, to the reminiscences needing time before they could attain sufficient vividness – we evolved the following procedure. I used to visit her in the morning and hypnotize her. (Very simple methods of doing this were arrived at empirically.) I would next ask her to concentrate her thoughts on the symptom we were treating at the moment and to tell me the occasions on which it had appeared. The patient would proceed to describe in rapid succession and under brief headings the external events concerned and these I would jot down. During her subsequent evening hypnosis she would then, with the help of my notes, give me a fairly detailed account of these circumstances.

An example will show the exhaustive manner in which she accomplished this. It was our regular experience that the patient did not hear when she was spoken to. It was possible to differentiate this passing habit of not hearing as follows:

(*a*) Not hearing when someone came in, while her thoughts were abstracted. One hundred and eight separate detailed instances of this, mentioning the persons and circumstances, often with dates. First instance: not hearing her father come in.

(*b*) Not understanding when several people were talking. Twenty-seven instances. First instance: her father, once more, and an acquaintance.

(*c*) Not hearing when she was alone and directly addressed. Fifty instances. Origin: her father having vainly asked her for some wine.

(*d*) Deafness brought on by being shaken (in a carriage, etc.). Fifteen instances. Origin: having been shaken angrily by her young brother when he caught her one night listening at the sick-room door.

(*e*) Deafness brought on by fright at a noise. Thirty-seven instances. Origin: a choking fit of her father's, caused by swallowing the wrong way.

1 [See footnote 3, p. 44 below.]

(*f*) Deafness during deep *absence*. Twelve instances.

(*g*) Deafness brought on by listening hard for a long time, so that when she was spoken to she failed to hear. Fifty-four instances.

Of course all these episodes were to a great extent identical insofar as they could be traced back to states of abstraction or *absences* or to
[37] fright. But in the patient's memory they were so clearly differentiated that if she happened to make a mistake in their sequence she would be obliged to correct herself and put them in the right order; if this was not done her report came to a standstill. The events she described were so lacking in interest and significance and were told in such detail that there could be no suspicion of their having been invented. Many of these incidents consisted of purely internal experiences and so could not be verified; others of them (or circumstances attending them) were within the recollection of people in her environment.

This example, too, exhibited a feature that was always observable when a symptom was being 'talked away': the particular symptom emerged with greater force while she was discussing it. Thus during the analysis of her not being able to hear she was so deaf that for part of the time I was obliged to communicate with her in writing.[1] The first provoking cause was habitually a fright of some kind, experienced while she was nursing her father – some oversight on her part, for instance.

The work of remembering was not always an easy matter and sometimes the patient had to make great efforts. On one occasion our whole progress was obstructed for some time because a recollection refused to emerge. It was a question of a particularly terrifying hallucination. While she was nursing her father she had seen him with a death's head. She and the people with her remembered that once, while she still appeared to be in good health, she had paid a visit to one of her relatives. She had opened the door and all at once fallen down unconscious. In order to get over the obstruction to our progress she visited the same place again and, on entering the room, again fell to the ground unconscious. During her subsequent evening hypnosis the obstacle was surmounted. As she came into the room, she had seen her pale face reflected in a mirror hanging opposite the door; but it was not herself that she saw but her father with a death's head. – We often noticed that her dread of a memory, as in the present instance, inhibited its emergence, and this had to be brought about forcibly by the patient or physician.

1 [This phenomenon is discussed at some length by Freud below (p. 263 f.), where he describes it as a symptom 'joining in the conversation'.]

The following incident, among others, illustrates the high degree of logical consistency of her states. During this period, as has already been [38] explained, the patient was always in her *condition seconde* – that is, in the year 1881 – at night. On one occasion she woke up during the night, declaring that she had been taken away from home once again, and became so seriously excited that the whole household was alarmed. The reason was simple. During the previous evening the talking cure had cleared up her disorder of vision, and this applied also to her *condition seconde*. Thus when she woke up in the night she found herself in a strange room, for her family had moved house in the spring of 1881. Disagreeable events of this kind were avoided by my always (at her request) shutting her eyes in the evening and giving her a suggestion that she would not be able to open them till I did so myself on the following morning. The disturbance was only repeated once, when the patient cried in a dream and opened her eyes on waking up from it.

Since this laborious analysis of her symptoms dealt with the summer months of 1880, which was the preparatory period of her illness, I obtained complete insight into the incubation and pathogenesis of this case of hysteria, and I will now describe them briefly.

In July, 1880, while he was in the country, her father fell seriously ill of a subpleural abscess. Anna shared the duties of nursing him with her mother. She once woke up during the night in great anxiety about the patient, who was in a high fever; and she was under the strain of expecting the arrival of a surgeon from Vienna who was to operate. Her mother had gone away for a short time and Anna was sitting at the bedside with her right arm over the back of her chair. She fell into a waking dream and saw a black snake coming towards the sick man from the wall to bite him. (It is most likely that there were, in fact, snakes in the field behind the house and that these had previously given the girl a fright; they would thus have provided the material for her hallucination.) She tried to keep the snake off, but it was as though she was paralysed. Her right arm, over the back of the chair, had gone to sleep and had become anaesthetic and paretic; and when she looked at it the fingers turned into little snakes with death's heads (the nails). (It seems probable that she had tried to use her paralysed right arm to drive off the snake and that its anaesthesia and paralysis had consequently become associated with the hallucination of the snake.) When the snake vanished, in her terror she tried to pray. But language failed her: she could [39] find no tongue in which to speak, till at last she thought of some children's verses in English[1] and then found herself able to think and pray

1 [In the 'Preliminary Communication' (p. 4 above) what she thought of is described as a prayer. This, of course, involves no contradiction.]

in that language. The whistle of the train that was bringing the doctor whom she expected broke the spell.

Next day, in the course of a game, she threw a quoit into some bushes; and when she went to pick it out, a bent branch revived her hallucination of the snake, and simultaneously her right arm became rigidly extended. Thenceforward the same thing invariably occurred whenever the hallucination was recalled by some object with a more or less snake-like appearance. This hallucination, however, as well as the contracture only appeared during the short *absences* which became more and more frequent from that night onwards. (The contracture did not become stabilized until December, when the patient broke down completely and took to her bed permanently.) As a result of some particular event which I cannot find recorded in my notes and which I no longer recall, the contracture of the right leg was added to that of the right arm.

Her tendency to autohypnotic *absences* was from now on established. On the morning after the night I have described, while she was waiting for the surgeon's arrival, she fell into such a fit of abstraction that he finally arrived in the room without her having heard his approach. Her persistent anxiety interfered with her eating and gradually led to intense feelings of nausea. Apart from this, indeed, each of her hysterical symptoms arose during an affect. It is not quite certain whether in every case a momentary state of *absence* was involved, but this seems probable in view of the fact that in her waking state the patient was totally unaware of what had been going on.

Some of her symptoms, however, seem not to have emerged in her *absences* but merely in an affect during her waking life; but if so, they recurred in just the same way. Thus we were able to trace back all of her different disturbances of vision to different, more or less clearly determining causes. For instance, on one occasion, when she was sitting by her father's bedside with tears in her eyes, he suddenly asked her what time it was. She could not see clearly; she made a great effort, and
[40] brought her watch near to her eyes. The face of the watch now seemed very big – thus accounting for her macropsia and convergent squint. Or again, she tried hard to suppress her tears so that the sick man should not see them.

A dispute, in the course of which she suppressed a rejoinder, caused a spasm of the glottis, and this was repeated on every similar occasion.

She lost the power of speech (*a*) as a result of fear, after her first hallucination at night, (*b*) after having suppressed a remark another time (by active inhibition), (*c*) after having been unjustly blamed for

something and (*d*) on every analogous occasion (when she felt mortified). She began coughing for the first time when once, as she was sitting at her father's bedside, she heard the sound of dance music coming from a neighbouring house, felt a sudden wish to be there, and was overcome with self-reproaches. Thereafter, throughout the whole length of her illness she reacted to any markedly rhythmical music with a *tussis nervosa*.

I cannot feel much regret that the incompleteness of my notes makes it impossible for me to enumerate all the occasions on which her various hysterical symptoms appeared. She herself told me them in every single case, with the one exception I have mentioned [p. 32 f. above, also below, p. 41]; and, as I have already said, each symptom disappeared after she had described its first occurrence.

In this way, too, the whole illness was brought to a close. The patient herself had formed a strong determination that the whole treatment should be finished by the anniversary of the day on which she was moved into the country [June 7 (p. 25 above)]. At the beginning of June, accordingly, she entered into the 'talking cure' with the greatest energy. On the last day – by the help of rearranging the room so as to resemble her father's sick-room – she reproduced the terrifying hallucination which I have described above and which constituted the root of her whole illness. During the original scene she had only been able to think and pray in English; but immediately after its reproduction she was able to speak German. She was moreover free from the innumerable disturbances which she had previously exhibited.[1] After this she left Vienna and travelled for a while; but it was a considerable time before she [41] regained her mental balance entirely. Since then she has enjoyed complete health.[2]

1 [At this point (so Freud once told James Strachey, with his finger on an open copy of the book) there is a hiatus in the text. What he had in mind and went on to describe was the occurrence which marked the end of Anna O.'s treatment. He made short allusions to it at the beginning of his 'History of the Psychoanalytic Movement' (1914*d*), *RSE*, **14**, 9–10, where he spoke of it as, from Breuer's point of view, an 'untoward event', and in Chapter II of his *Autobiographical Study* (1925*d*), ibid., **20**. The whole story is told by Ernest Jones in his life of Freud (1953, **1**, 246 ff.), and it is enough to say here that, when the treatment had apparently reached a successful end, the patient suddenly made manifest to Breuer the presence of a strong unanalysed positive transference of an unmistakably sexual nature. It was this occurrence, Freud believed, that caused Breuer to hold back the publication of the case history for so many years and that led ultimately to his abandonment of all further collaboration in Freud's researches. A much fuller account is given in Freud (1960*a*, Letter 265).]

2 [Cf. footnote, p. 30 f. above.]

Although I have suppressed a large number of quite interesting details, this case history of Anna O. has grown bulkier than would seem to be required for a hysterical illness that was not in itself of an unusual character. It was, however, impossible to describe the case without entering into details, and its features seem to me of sufficient importance to excuse this extensive report. In just the same way, the eggs of the echinoderm are important in embryology, not because the sea urchin is a particularly interesting animal but because the protoplasm of its eggs is transparent and because what we observe in them thus throws light on the probable course of events in eggs whose protoplasm is opaque.[1] The interest of the present case seems to me above all to reside in the extreme clarity and intelligibility of its pathogenesis.

There were two psychical characteristics present in the girl while she was still completely healthy which acted as predisposing causes for her subsequent hysterical illness:

(1) Her monotonous family life and the absence of adequate intellectual occupation left her with an unemployed surplus of mental liveliness and energy, and this found an outlet in the constant activity of her imagination.

(2) This led to a habit of daydreaming (her 'private theatre'), which laid the foundations for a dissociation of her mental personality. Nevertheless, a dissociation of this degree is still within the bounds of
[42] normality. Reveries and reflections during a more or less mechanical occupation do not in themselves imply a pathological splitting of consciousness, since if they are interrupted – if, for instance, the subject is spoken to – the normal unity of consciousness is restored; nor, presumably, is any amnesia present. In the case of Anna O., however, this habit prepared the ground upon which the affect of anxiety and dread [*Angst- und Erwartungsaffekt*] was able to establish itself in the way I have described, when once that affect had transformed the patient's habitual daydreaming into a hallucinatory *absence*. It is remarkable how completely the earliest manifestation of her illness in its beginnings already exhibited its main characteristics, which afterwards remained unchanged for almost two years. These comprised the existence of a second state of consciousness which first emerged as a temporary *absence* and later became organized into a '*double conscience*'; an inhibition of speech, determined by the affect of anxiety, which found a chance discharge in the English verses; later on, paraphasia and loss of her mother tongue, which was replaced by excellent English; and lastly the accidental

1 [This same analogy was similarly used by Freud many years later (Freud, 1913*b*; *RSE*, **13**, 185).]

paralysis of her right arm, due to pressure, which later developed into a contractural paresis and anaesthesia on her right side. The mechanism by which this latter affection came into being agreed entirely with Charcot's theory of traumatic hysteria – a slight trauma occurring during a state of hypnosis.

But whereas the paralysis experimentally provoked by Charcot in his patients became stabilized immediately, and whereas the paralysis caused in sufferers from traumatic neuroses by a severe traumatic shock sets in at once, the nervous system of this girl put up a successful resistance for four months. Her contracture, as well as the other disturbances which accompanied it, set in only during the short *absences* in her *condition seconde* and left her during her normal state in full control of her body and possession of her senses; so that nothing was noticed either by herself or by those around her, though it is true that the attention of the latter was centred upon the patient's sick father and was consequently diverted from her.

Since, however, her *absences* with their total amnesia and accompanying hysterical phenomena grew more and more frequent from the time of her first hallucinatory autohypnosis, the opportunities multiplied for the formation of new symptoms of the same kind, and those that had already been formed became more strongly entrenched by frequent [43]
repetition. In addition to this, it gradually came about that any sudden distressing affect would have the same result as an *absence* (though, indeed, it is possible that such affects actually *caused* a temporary *absence* in every case); chance coincidences set up pathological associations and sensory or motor disturbances, which thenceforward appeared along with the affect. But hitherto this only occurred for fleeting moments. Before the patient took permanently to her bed she had already developed the whole assemblage of hysterical phenomena, without anyone knowing it. It was only after the patient had broken down completely owing to exhaustion brought about by lack of nourishment, insomnia and constant anxiety, and only after she had begun to pass more time in her *condition seconde* than in her normal state, that the hysterical phenomena extended to the latter as well and changed from intermittent acute symptoms into chronic ones.

The question now arises how far the patient's statements are to be trusted and whether the occasions and mode of origin of the phenomena were really as she represented them. So far as the more important and fundamental events are concerned, the trustworthiness of her account seems to me to be beyond question. As regards the symptoms

disappearing after being 'talked away', I cannot use this as evidence; it may very well be explained by suggestion. But I always found the patient entirely truthful and trustworthy. The things she told me were intimately bound up with what was most sacred to her. Whatever could be checked by other people was fully confirmed. Even the most highly gifted girl would be incapable of concocting a tissue of data with such a degree of internal consistency [*grosse innere Logik*][t] as was exhibited in the history of this case. It cannot be disputed, however, that precisely her consistency may have led her (in perfectly good faith) to assign to some of her symptoms a precipitating cause which they did not in fact possess. But this suspicion, too, I consider unjustified. The very insignificance of so many of those causes, the irrational character of so many of the connections involved, argue in favour of their reality. The patient could not understand how it was that dance music made her cough; such a construction is too meaningless to have been deliberate. (It seemed very likely to me, incidentally, that each of her twinges of
[44] conscience brought on one of her regular spasms of the glottis and that the motor impulses which she felt – for she was very fond of dancing – transformed the spasm into a *tussis nervosa*.) Accordingly, in my view the patient's statements were entirely trustworthy and corresponded to the facts.

And now we must consider how far it is justifiable to suppose that hysteria is produced in an analogous way in other patients, and that the process is similar where no such clearly distinct *condition seconde* has become organized. I may advance in support of this view the fact that in the present case, too, the story of the development of the illness would have remained completely unknown alike to the patient and the physician if it had not been for her peculiarity of remembering things in hypnosis, as I have described, and of relating what she remembered. While she was in her waking state she knew nothing of all this. Thus it is impossible to arrive at what is happening in other cases from an examination of the patients while in a waking state, for with the best will in the world they can give one no information. And I have already pointed out how little those surrounding the present patient were able to observe of what was going on. Accordingly, it would only be possible to discover the state of affairs in other patients by means of some such procedure as was provided in the case of Anna O. by her autohypnoses. Provisionally we can only express the view that trains of events similar to those here described occur more commonly than our ignorance of the pathogenic mechanism concerned has led us to suppose.

When the patient had become confined to her bed, and her consciousness was constantly oscillating between her normal and her 'secondary' state, the whole host of hysterical symptoms, which had arisen separately and had hitherto been latent, became manifest, as we have already seen, as chronic symptoms. There was now added to these a new group of phenomena which seemed to have had a different origin: the paralytic contractures of her left extremities and the paresis of the muscles raising her head. I distinguish them from the other phenomena because when once they had disappeared they never returned, even in the briefest or mildest form or during the concluding and recuperative phase, when all the other symptoms became active again after having been in abeyance for some time. In the same way, they never came up in the hypnotic analyses and were not traced back to emotional or [45] imaginative sources. I am therefore inclined to think that their appearance was not due to the same psychical process as was that of the other symptoms, but is to be attributed to a secondary extension of that unknown condition which constitutes the somatic foundation of hysterical phenomena.[1]

Throughout the entire illness her two states of consciousness persisted side by side: the primary one in which she was quite normal psychically, and the secondary one which may well be likened to a dream in view of its wealth of imaginative products and hallucinations, its large gaps of memory and the lack of inhibition and control in its associations. In this secondary state the patient was in a condition of alienation. The fact that the patient's mental condition was entirely dependent on the intrusion of this secondary state into the normal one seems to throw considerable light on at least one class of hysterical psychosis. Every one of her hypnoses in the evening afforded evidence that the patient was entirely clear and well ordered in her mind and normal as regards her feeling and volition so long as none of the products of her secondary state was acting as a stimulus 'in the unconscious'.[2] The extremely

1 [See footnote, p. 30 f. above.]

2 [This seems to be the first published occurrence of the term '*das Unbewusste*' ('the unconscious') in what was to be its psychoanalytic sense. It had, of course, often been used previously by other writers, particularly by philosophers (e.g. Hartmann, 1869). The fact that Breuer puts it in quotation marks may possibly indicate that he is attributing it to Freud. The term is used by Freud himself below, e.g. on p. 67 *n*. 2. The adjectival form '*unbewusst*' ('unconscious') had been used some years earlier in an unpublished draft drawn up in November, 1892, jointly by Breuer & Freud (Freud, 1940*d*). Freud had used the term '*le subconscient*' in a French paper on motor paralyses (1893*c*) and uses '*unterbewusst*' ('subconscious') in the present work (p. 61 *n*. below), as does Breuer very much more frequently (e.g. p. 198 below). Freud already objected to the use of this term in *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 549, and did so later, for instance, in his paper on 'The Unconscious' (1915*e*), ibid., **14**, 151.]

marked psychosis which appeared whenever there was any considerable interval in this unburdening process showed the degree to which those products influenced the psychical events of her 'normal' state. It is hard to avoid expressing the situation by saying that the patient was split into two personalities of which one was mentally normal and the other insane. The sharp division between the two states in the present patient only exhibits more clearly, in my opinion, what has given rise to a number of unexplained problems in many other hysterical patients. It was especially noticeable in Anna O. how much the products of her 'bad self', as she herself called it, affected her moral habit of mind. If these products had not been continually disposed of, we should have been faced with a hysteric of the malicious type – refractory, lazy, disagreeable and ill-natured; but, as it was, after the removal of those stimuli her true character, which was the opposite of all these, always reappeared at once.

[46]

Nevertheless, though her two states were thus sharply separated, not only did the secondary state intrude into the first one, but – and this was at all events frequently true, and even when she was in a very bad condition – a clear-sighted and calm observer sat, as she put it, in a corner of her brain and looked on at all the mad business. This persistence of clear thinking while the psychosis was actually going on found expression in a very curious way. At a time when, after the hysterical phenomena had ceased, the patient was passing through a temporary depression, she brought up a number of childish fears and self-reproaches, and among them the idea that she had not been ill at all and that the whole business had been simulated. Similar observations, as we know, have frequently been made. When a disorder of this kind has cleared up and the two states of consciousness have once more become merged into one, the patients, looking back to the past, see themselves as the single undivided personality which was aware of all the nonsense; they think they could have prevented it if they had wanted to, and thus they feel as though they had done all the mischief deliberately. – It should be added that this normal thinking which persisted during the secondary state must have fluctuated enormously in its amount and must very often have been completely absent.

I have already described the astonishing fact that from beginning to end of the illness all the stimuli arising from the secondary state, together with their consequences, were permanently removed by being given verbal utterance in hypnosis, and I have only to add an assurance that this was not an invention of mine which I imposed on the patient

by suggestion. It took me completely by surprise, and not until symptoms had been got rid of in this way in a whole series of instances did I develop a therapeutic technique out of it.

The final cure of the hysteria deserves a few more words. It was [47] accompanied, as I have already said, by considerable disturbances and a deterioration in the patient's mental condition. I had a very strong impression that the numerous products of her secondary state which had been quiescent were now forcing their way into consciousness; and though in the first instance they were being remembered only in her secondary state, they were nevertheless burdening and disturbing her normal one. It remains to be seen whether it may not be that the same origin is to be traced in other cases in which a chronic hysteria terminates in a psychosis.[1]

1 [A very full summary and discussion of this case history occupies the greater part of the first of Freud's *Five Lectures* (1910*a*), *RSE*, **11**, 11 ff.]

CASE 2
FRAU EMMY VON N., AGE 40, FROM LIVONIA[1] (*FREUD*)

[48] On May 1, 1889,[2] I took on the case of a lady of about forty years of age, whose symptoms and personality interested me so greatly that I devoted a large part of my time to her and determined to do all I could for her recovery. She was a hysteric and could be put into a state of somnambulism with the greatest ease; and when I became aware of this I decided that I would make use of Breuer's technique of investigation under hypnosis, which I had come to know from the account he had given me of the successful treatment of his first patient. This was my first attempt at handling that therapeutic method [pp. 92 *n*. 3 and 253 below]. I was still far from having mastered it; in fact I did not carry the analysis[3] of the symptoms far enough, nor pursue it systematically enough. I shall perhaps be able best to give a picture of the patient's condition and my medical procedure by reproducing the notes which I made each evening during the first three weeks of the treatment. Wherever later experience has brought me a better understanding, I shall embody it in footnotes and interpolated comments.

May 1, 1889. This lady, when I first saw her, was lying on a sofa with her head resting on a leather cushion. She still looked young and had finely cut features, full of character. Her face bore a strained and painful expression, her eyelids were drawn together and her eyes cast down; there was a heavy frown on her forehead and the nasolabial folds were deep. She spoke in a low voice as though with difficulty and her speech
[49] was from time to time subject to spastic interruptions amounting to a stammer. She kept her fingers, which exhibited a ceaseless agitation

1 [This case history had already been discussed briefly by Freud in his paper on 'A Case of Successful Treatment by Hypnotism' (1892–93*a*), *RSE*, **1**, 151 f., and he made a short allusion to it in the first of his *Five Lectures* (1910*a*), ibid., **11**, 17. The biographical details provided in the editorial footnotes below derive mainly from Andersson (1979).]

2 [The chronology of this case history is self-contradictory as it stands. The dates which are given in all the German editions have been retained in the present translation, but they are in need of correction. The question is fully discussed in Appendix A (p. 309 f. below).]

3 [Freud had already used the term 'analysis' (as well as 'psychical analysis', 'psychological analysis' and 'hypnotic analysis') in his first paper on 'The Neuropsychoses of Defence' (1894*a*), *RSE*, **3**. The term 'analysed' appears in the 'Preliminary Communication' of 1893, p. 7 above. He only later introduced the word 'psychoanalysis' in a paper on the aetiology of the neuroses, written in French (1896*a*), *RSE*, **3**.]

resembling athetosis, tightly clasped together. There were frequent convulsive tic-like movements of her face and the muscles of her neck, during which some of them, especially the right sterno-cleido-mastoid, stood out prominently. Furthermore she frequently interrupted her remarks by producing a curious 'clacking' sound from her mouth which defies imitation.[1]

What she told me was perfectly coherent and revealed an unusual degree of education and intelligence. This made it seem all the more strange when every two or three minutes she suddenly broke off, contorted her face into an expression of horror and disgust, stretched out her hand towards me, spreading and crooking her fingers, and exclaimed, in a changed voice, charged with anxiety: 'Keep still! – Don't say anything! – Don't touch me!' She was probably under the influence of some recurrent hallucination[2] of a horrifying kind and was keeping the intruding material at bay with this formula.[3] These interpolations came to an end with equal suddenness and the patient took up what she had been saying, without pursuing her momentary excitement any further, and without explaining or apologizing for her behaviour – probably, therefore, without herself having noticed the interpolation.[4]

I learnt what follows of her circumstances. Her family came from Central Germany, but had been settled for two generations in the Baltic provinces of Russia, where it possessed large estates. She was one of fourteen children,[5] of which she herself was the thirteenth. Only four of them survived. She was brought up carefully, but under strict discipline [*Zwang*][T] by an over-energetic and severe mother. When she was twenty-three she married an extremely gifted and able man who had [50]
made a high position for himself as an industrialist on a large scale, but

1 This 'clacking' was made up of a number of sounds. Colleagues of mine with sporting experience told me, on hearing it, that its final notes resembled the call of a capercaillie [according to Fisher (1955) 'a ticking ending with a pop and a hiss'].

2 [See footnote 1, p. 20 above.]

3 These words did in fact represent a protective formula, and this will be explained later on. Since then I have come across similar protective formulas in a melancholic woman who endeavoured by their means to control her tormenting thoughts – wishes that something bad might happen to her husband and her mother, blasphemies, etc.

4 What we had here was a hysterical delirium which alternated with normal consciousness, just as a true tic intrudes into a voluntary movement without interfering with it and without being mixed up with it.

5 [Actually thirteen, according to Andersson's (1979) research. Her family lived in Switzerland (not Russia) but one of her ancestors had been knighted by a German king, so they belonged to both the Swiss community and the German nobility. Freud altered numerous details to protect his patient's identity.]

was much older than her.[1] After a short marriage he died of a heart attack.[2] To this event, together with the task of bringing up her two daughters, now sixteen and fourteen years old, who were often ailing and suffered from nervous troubles, she attributed her own illness. Since her husband's death, fourteen years ago, she had been constantly ill with varying degrees of severity. Four years ago her condition was temporarily improved by a course of massage combined with electric baths. Apart from this, all her efforts to regain her health have been unsuccessful. She has travelled a great deal and has many lively interests. She lives at present in a country seat on the Baltic near a large town.[3] For several months she has once more been very ill, suffering from depression and insomnia, and tormented with pains; she went to Abbazia[4] in the vain hope of improvement, and for the last six weeks has been in Vienna, up till now in the care of a physician of outstanding merit.

I suggested that she should separate from the two girls, who had their governess, and go into a nursing home, where I could see her every day. This she agreed to without raising the slightest objection.

On the evening of *May 2* I visited her in the nursing home. I noticed that she started violently whenever the door opened unexpectedly. I therefore arranged that the nurses and the house physicians, when they visited her, should give a loud knock at her door and not enter till she had told them to come in. But even so, she still made a grimace and gave a jump every time anyone entered.

Her chief complaint today was of sensations of cold and pain in her left leg which proceeded from her back above the iliac crest. I ordered her to be given warm baths and I shall massage her whole body twice a day.

She is an excellent subject for hypnotism. I had only to hold up a finger in front of her and order her to go to sleep, and she sank back
[51] with a dazed and confused look. I suggested that she should sleep well, that all her symptoms should get better, and so on. She heard all this with closed eyes but with unmistakably concentrated attention; and her features gradually relaxed and took on a peaceful appearance. After this first hypnosis she retained a dim memory of my words; but already at

1 [He was 40 years older. Following his death his children from a previous marriage – who were older than his new wife – accused her of having poisoned him. This wholly unsubstantiated allegation persisted for decades and marred Emmy von N.'s life. See p. 57 below.]

2 [*Herzschlage*. Mistranslated as 'stroke' in the *SE*.]

3 [This was actually a castle on a Swiss lake. It is referred to later as 'D——'.]

4 [The (at that time) Austrian resort on the Adriatic.]

the second there was complete somnambulism (with amnesia). I had warned her that I proposed to hypnotize her, to which she raised no difficulty. She has not previously been hypnotized, but it is safe to suppose that she has read about hypnotism, though I cannot tell what notions she may have about the hypnotic state.[1]

This treatment by warm baths, massage twice a day and hypnotic suggestion was continued for the next few days. She slept well, got visibly better, and passed most of the day lying quietly in bed. She was not forbidden to see her children, to read, or to deal with her correspondence.

May 8, morning. She entertained me, in an apparently quite normal state, with gruesome stories about animals. She had read in the *Frankfurter Zeitung*, which lay on the table in front of her, a story of how an apprentice had tied up a boy and put a white mouse into his mouth. The boy had died of fright. Dr K. had told her that he had sent a whole case of white rats to Tiflis. As she told me this she demonstrated every sign of horror. She clenched and unclenched her hand several times. 'Keep still! – Don't say anything! – Don't touch me! – Supposing a creature like that was in the bed!' (She shuddered.) 'Only think, when it's unpacked! There's a dead rat in among them – one that's been gn-aw-aw-ed at!'

During the hypnosis I tried to disperse these animal hallucinations. While she was asleep I picked up the *Frankfurter Zeitung*. I found the anecdote about the boy being maltreated, but without any reference to [52] mice or rats. So she had introduced these from her delirium while she was reading. (I told her in the evening of our conversation about the white mice. She knew nothing of it, was very much astonished and laughed heartily.[2])

1 Every time she woke from hypnosis she looked about her for a moment in a confused way, let her eyes fall on me, seemed to have come to her senses, put on her glasses, which she took off before going to sleep, and then became quite lively and on the spot. Although in the course of the treatment (which lasted for seven weeks in this first year and eight in the second) we discussed every sort of subject, and although I put her to sleep twice almost every day, she never made any comment to me about the hypnosis or asked me a single question about it; and in her waking state she seemed, so far as possible, to ignore the fact that she was undergoing hypnotic treatment.

2 A sudden interpolation like this of a delirium into a waking state was not uncommon with her and was often repeated later in my presence. She used to complain that in conversation she often gave the most absurd answers, so that people did not understand her. On the occasion when I first visited her I asked her how old she was and she answered quite seriously: 'I am a woman dating from last century.' Some weeks later she explained to me she had been thinking at the time in her delirium of a beautiful old cupboard which, as a connoisseur of old furniture, she had bought in the course of her travels. It was to this cupboard that her answer had referred when my question about her age raised the topic of dates.

During the afternoon she had what she called a 'neck cramp',[1] which, however, as she said, 'only lasted a short time – a couple of hours'.

Evening. I requested her, under hypnosis, to talk, which, after some effort, she succeeded in doing. She spoke softly and reflected for a moment each time before answering. Her expression altered according to the subject of her remarks, and grew calm as soon as my suggestion had put an end to the impression made upon her by what she was saying. I asked her why it was that she was so easily frightened, and she answered: 'It has to do with memories of my earliest youth.' 'When?' 'First when I was five years old and my brothers and sisters often threw dead animals at me. That was when I had my first fainting fit and spasms. But my aunt said it was disgraceful and that I ought not to have attacks like that, and so they stopped. Then I was frightened again when I was seven and I unexpectedly saw my sister in her coffin;[2] and again when I was eight and my brother terrified me so often by dressing up in sheets like a ghost; and again when I was nine and I saw my aunt in her coffin and her jaw suddenly dropped.'

This series of traumatic precipitating causes which she produced in answer to my question why she was so liable to fright was clearly ready to hand in her memory. She could not have collected these episodes from different periods of her childhood so quickly during the short
[53] interval which elapsed between my question and her answer. At the end of each separate story she twitched all over and took on a look of fear and horror. At the end of the last one she opened her mouth wide and panted for breath. The words in which she described the terrifying subject matter of her experience were pronounced with difficulty and between gasps. Afterwards her features became peaceful.

In reply to a question she told me that while she was describing these scenes she saw them before her, in a plastic form and in their natural colours. She said that in general she thought of these experiences very often and had done so in the last few days. Whenever this happened she saw these scenes with all the vividness of reality.[3] I now understand why she entertains me so often with animal scenes and pictures of corpses. My therapy consists in wiping away these pictures, so that she is no longer able to see them before her. To give support to my suggestion I stroked her several times over the eyes.

1 A species of migraine. [See p. 63 *n*. 1 below.]

2 [Four of her siblings died before she was born in 1848. Two others died as infants, another at the age of thirteen (when Emmy was aged between two and six), a sister at fifteen (when Emmy was eighteen) and a brother at age thirty-three (no doubt the one mentioned below on pp. 49 and 52) when Emmy was twenty – although Freud implies she was nineteen when this brother died, perhaps to protect her identity (see Appendix A, p. 309 below).]

3 Many other hysterical patients have reported to us that they have memories of this kind in vivid visual pictures and that this applied especially to their pathogenic memories.

May 9 [morning].[1] Without my having given her any further suggestion, she had slept well. But she had gastric pains in the morning. They came on yesterday in the garden where she stayed out too long with her children. She agreed to my limiting the children's visits to two and a half hours. A few days ago she had reproached herself for leaving the children by themselves. I found her in a somewhat excited state today; her forehead was lined, her speech was halting and she made her clacking noises. While she was being massaged she told me only that the children's governess had brought her an ethnological atlas and that some pictures in it of American Indians dressed up as animals had given her a great shock. 'Only think, if they came to life!' (She shuddered.)

Under hypnosis I asked why she had been so much frightened by these pictures, since she was no longer afraid of animals. She said they had reminded her of visions she had had (when she was nineteen) at the time of her brother's death. (I shall hold over enquiring into this memory until later.) I then asked her whether she had always spoken with a [54]
stammer and how long she had had her tic (the peculiar clacking sound).[2] Her stammering, she said, had come on while she was ill; she had had the tic for the last five years, ever since a time when she was sitting by the bedside of her younger daughter who was very ill, and had wanted to keep absolutely *quiet*. I tried to reduce the importance of this memory, by pointing out that after all nothing had happened to her daughter, and so on. The thing came on, she said, whenever she was apprehensive or frightened. I instructed her not to be frightened of the pictures of the Red Indians but to laugh heartily at them and even to draw my attention to them. And this did in fact happen after she had woken up: she looked at the book, asked whether I had seen it, opened it at the page and laughed out loud at the grotesque figures, without a trace of fear and without any strain in her features. Dr Breuer came in suddenly with the house physician to visit her. She was frightened and began to make her clacking noise, so that they soon left us. She explained that she was so much agitated because she was unpleasantly affected by the fact that the house physician came in every time as well.

I had also got rid of her gastric pains during the hypnosis by stroking her, and I told her that though she would expect the pain to return after her midday meal it would not do so.

1 [All the German editions read 'evening', which in view of what follows seems certainly to be a mistake.]

2 I had already asked her this question about the tic during her waking state, and she had replied: 'I don't know; oh, a very long time.'

Evening. For the first time she was cheerful and talkative and gave evidence of a sense of humour that I should not have expected in such a serious woman; and, among other things, in the strong feeling that she was better, she made fun of her treatment by my medical predecessor. She had long intended, she said, to give up that treatment but had not been able to find the right method of doing so till a chance remark made by Dr Breuer, when he visited her once, showed her a way out. When I seemed to be surprised at this, she grew frightened and began to blame herself very severely for having been indiscreet. But I was able, it seemed, to reassure her. – She had had no gastric pains, though she had expected them.

Under hypnosis I asked her to tell me further experiences which had given her a lasting fright. She produced a second series of this kind, dating from her later youth, with as much promptitude as the first series
[55] and she assured me once more that all these scenes appeared before her often, vividly and in colours. One of them was of how she saw a female cousin taken off to an insane asylum (when she was fifteen). She tried to call for help but was unable to, and lost her power of speech till the evening of the same day. Since she talked so often about asylums in her waking state, I interrupted her and asked on what other occasions she had been concerned with insanity. She told me that her mother had herself been in an asylum for some time. They had once had a maid-servant one of whose previous mistresses had spent a long time in an asylum and who used to tell her horrifying stories of how the patients were tied to chairs, beaten, and so on. As she told me this she clenched her hands in horror; she saw all this before her eyes. I endeavoured to correct her ideas about insane asylums, and assured her that she would be able to hear about institutions of this kind without referring them to herself. At this, her features relaxed.

She continued her list of terrifying memories. One, at fifteen, of how she found her mother, who had had a stroke, lying on the floor (her mother lived for another four years); again, at nineteen, how she came home one day and found her mother dead, with a distorted face. I naturally had considerable difficulty in mitigating these memories. After a rather lengthy explanation, I assured her that this picture, too, would only appear to her again indistinctly and without strength. – Another memory was how, at nineteen, she lifted up a stone and found a toad under it, which made her lose her power of speech for hours afterwards.[1]

1 A special kind of symbolism must, no doubt, have lain behind the toad, but I unfortunately neglected to enquire into it.

During this hypnosis I convinced myself that she knew everything that happened in the last hypnosis, whereas in waking life she knows nothing of it.

May 10, morning. For the first time today she was given a bran bath instead of her usual warm bath. I found her looking cross and with a pinched face, with her hands wrapped in a shawl. She complained of cold and pains. When I asked her what was the matter, she told me that the bath had been uncomfortably short to sit in and had brought on pains. During the massage she started by saying that she still felt badly about having given Dr Breuer away yesterday. I pacified her with a white lie and said that I had known about it all along, where- [56]
upon her agitation (clacking, grimaces) ceased. So each time, even while I am massaging her, my influence has already begun to affect her; she grows quieter and clearer in the head, and even without questioning under hypnosis can discover the cause of her ill-humour on that day. Nor is her conversation during the massage so aimless as would appear. On the contrary, it contains a fairly complete reproduction of the memories and new impressions which have affected her since our last talk, and it often leads on, in a quite unexpected way, to pathogenic reminiscences of which she unburdens herself without being asked to. It is as though she had adopted my procedure and was making use of our conversation, apparently unconstrained and guided by chance, as a supplement to her hypnosis.[1] For instance, today she began talking about her family, and in a very roundabout way got on to the subject of a cousin. He was rather peculiar in the head and his parents had all his teeth pulled out at one sitting. She accompanied the story with horrified looks and kept repeating her protective formula ('Keep still! – Don't say anything! – Don't touch me!'). After this her face smoothed out and she became cheerful. Thus, her behaviour in waking life is directed by the experiences she has had during her somnambulism, in spite of her believing, while she is awake, that she knows nothing about them.

Under hypnosis I repeated my question as to what it was that had made her upset and I got the same answers but in the reverse order: (1) her indiscreet talk yesterday, and (2) her pains caused by her being so uncomfortable in the bath. – I asked her today the meaning of her phrase 'Keep still!', etc. She explained that when she had frightening thoughts she was afraid of their being interrupted in their course, because then

1 [This is perhaps the earliest appearance of what later became the method of free association.]

everything would get confused and things would be even worse. The 'Keep still!' related to the fact that the animal shapes which appeared to her when she was in a bad state started moving and began to attack her if anyone made a movement in her presence. The final injunction 'Don't touch me!' was derived from the following experiences. She told me how, when her brother had been so ill from taking a lot of morphine – she
[57] was nineteen at the time – he used often to seize hold of her; and how, another time, an acquaintance had suddenly gone mad in the house and had caught her by the arm; (there was a third, similar instance, which she did not remember exactly;) and lastly, how, when she was twenty-eight and her daughter was very ill, the child had caught hold of her so forcibly in its delirium that she was almost choked. Though these four instances were so widely separated in time, she told me them in a single sentence and in such rapid succession that they might have been a single episode in four acts. Incidentally, all the accounts she gave of traumas arranged like these in groups began with a 'how', the component traumas being separated by an 'and'. Since I noticed that the protective formula was designed to safeguard her against a recurrence of such experiences, I removed this fear by suggestion, and in fact I never heard the formula from her again.

Evening. I found her very cheerful. She told me, with a laugh, that she had been frightened by a small dog which barked at her in the garden. Her face was a little bit drawn, however, and there was some internal agitation which did not disappear until she had asked me whether I was annoyed by something she had said during the massage this morning and I had said 'no'. Her period began again today after an interval of scarcely a fortnight. I promised to regulate this by hypnotic suggestion and, under hypnosis, set the interval at 28 days.[1]

Under hypnosis, I also asked her whether she remembered the last thing she told me; in asking this what I had in mind was a task which had been left over from yesterday evening; but she began quite correctly with the 'don't touch me' from *this morning's* hypnosis. So I took her back to yesterday's topic. I had asked her the origin of her stammering and she had replied, 'I don't know'.[2] I had therefore requested her to remember it by the time of today's hypnosis. She accordingly answered me today without any further reflection but in great agitation and with
[58] spastic impediments to her speech: 'How the horses bolted once with

1 A suggestion which was carried out.

2 It is possible that this answer, 'I don't know', was correct; but it may quite as well have indicated reluctance to talk about the causes of the stammering. I have since observed in other patients that the greater the effort they have made to repress a thing from their consciousness the more difficulty they have in remembering it under hypnosis as well as in waking life.

the children in the carriage; and how another time I was driving through the forest with the children in a thunderstorm, and a tree just in front of the horses was struck by lightning and the horses shied and I thought: "You must keep quite still now, or your screaming will frighten the horses even more and the coachman won't be able to hold them in at all." It came on from that moment.' She was quite unusually excited as she told me this story. I further learnt from her that the stammer had begun immediately after the first of these two occasions, but had disappeared shortly afterwards and then came on for good after the second, similar occasion. I extinguished her plastic memory of these scenes, but asked her to imagine them once more. She appeared to try to do this and remained quiet as she did so; and from now on she spoke in the hypnosis without any spastic impediment.[1]

Finding her disposed to be communicative, I asked her what further events in her life had frightened her so much that they had left her with plastic memories. She replied by giving me a collection of such experiences: – [1] How a year after her mother's death, she was visiting a Frenchwoman who was a friend of hers, and had been sent into the next room with another girl to fetch a dictionary, and had then seen someone sit up in the bed who looked exactly like the woman she had just left behind in the other room. She went stiff all over and was rooted to the spot. She learnt afterwards that it was a specially arranged dummy. I said that what she saw had been a hallucination, and appealed to her good sense, and her face relaxed. [2] How she had nursed her sick brother and he had had such fearful attacks as a result of the morphine and had terrified her and seized hold of her. I remembered that she had already mentioned this experience this morning, and, as an experiment, I asked her on what other occasions this 'seizing hold' had happened. To my agreeable surprise she made a long pause this time before answering and then asked doubtfully 'My little girl?' She was quite unable to recall the other two occasions (see above [p. 52]). My prohibition – my expunging of her memories – had therefore been effective. – Further, [3] how, [59] while she was nursing her brother, her aunt's pale face had suddenly appeared over the top of the screen. She had come to convert him to Catholicism.

I saw that I had come to the root of her constant fear of surprises, and I asked for further instances of this. She went on: How they had a friend

1 As we see from this, the patient's tic-like clacking and her spastic stammer were two symptoms which went back to similar precipitating causes and had an analogous mechanism. I have already commented on this mechanism in a short paper on hypnotic treatment (1892–93*a*), and I shall also return to it below. [See p. 81 ff.]

staying at her home who liked slipping into the room very softly so that all of a sudden he was there; how she had been so ill after her mother's death and had gone to a health resort and a lunatic had walked into her room several times at night by mistake and come right up to her bed; and lastly, how, on the journey here from Abbazia a strange man had four times opened the door of her compartment suddenly and had fixed his eyes on her each time with a stare. She was so much terrified that she sent for the conductor.

I wiped out all these memories, woke her up and assured her she would sleep well tonight, having omitted to give her this suggestion in her hypnosis. The improvement of her general condition was shown by her remark that she had not done any reading today, she was living in such a happy dream – she, who always had to be doing something because of her inner unrest.

May 11, morning. Today she had an appointment with Dr N., the gynaecologist, who is to examine her elder daughter about her menstrual troubles. I found Frau Emmy in a rather disturbed state, though this was expressed in slighter physical signs than formerly. She called out from time to time: 'I'm afraid, so afraid, I think I shall die.' I asked her what she was afraid of? Was it of Dr N.? She did not know, she said; she was just afraid. Under hypnosis, which I induced before my colleague arrived, she declared that she was afraid she had offended me by something she had said during the massage yesterday which seemed to her to have been impolite. She was frightened of anything new, too, and consequently of the new doctor. I was able to soothe her, and though she started once or twice in the presence of Dr N., she behaved very well apart from this and produced neither her clacking noises nor any inhibition of speech. After he had gone I put her under hypnosis once more,
[60] to remove any possible residue of the excitement caused by his visit. She herself was very much pleased with her behaviour and put great hopes in the treatment; and I tried to convince her from this example that there is no need to be afraid of what is new, since it also contains what is good.[1]

Evening. She was very lively and unburdened herself of a number of doubts and scruples during our conversation before the hypnosis. Under hypnosis I asked her what event in her life had produced the most lasting effect on her and came up most often in her memory. Her husband's death, she said. I got her to describe this event to me in full detail, and

1 Didactic suggestions of this kind always missed fire with Frau Emmy, as will be seen from what follows.

this she did with every sign of deepest emotion but without any clacking or stammering: – How, she began, they had been at a place on the Riviera of which they were both very fond, and while they were crossing a bridge he had suddenly sunk to the ground and lain there lifeless for a few minutes but had then got up again and seemed quite well; how, a short time afterwards, as she was lying in bed after her second confinement, her husband, who had been sitting at breakfast at a small table beside her bed, reading a newspaper, had got up all at once, looked at her so strangely, taken a few paces forward and then fallen down dead; she had got out of bed, and the doctors who were called in had made efforts to revive him which she had heard from the next room; but it had been in vain. And, she then went on to say, how the baby, which was then a few weeks old, had been seized with a serious illness which had lasted for six months, during which she herself had been in bed with a high fever. – And there now followed in chronological order her grievances against this child, which she threw out rapidly with an angry look on her face, in the way one would speak of someone who had become a nuisance. This child, she said, had been very peculiar for a long time; it had screamed all the time and did not sleep, and it had developed a paralysis of the left leg which there had seemed very little hope of curing. When it was four it had had visions; it had been late in learning to walk and to talk, so that for a long time it had been believed to be imbecile. According to the doctors it had had encephalitis and inflammation of the spinal cord and she did not know what else besides. I interrupted her here and pointed out to her that this same child was [61] today a normal girl and in the bloom of health, and I made it impossible for her to see any of these melancholy things again, not only by wiping out her memories of them in their *plastic* form but by removing her whole recollection of them, as though they had never been present in her mind. I promised her that this would lead to her being freed from the expectation of misfortune which perpetually tormented her and from the pains all over her body, of which she had been complaining precisely during her narrative, after we had heard nothing of them for several days.[1]

1 On this occasion my energy seems to have carried me too far. When, as much as eighteen months later, I saw Frau Emmy again in a relatively good state of health, she complained that there were a number of most important moments in her life of which she had only the vaguest memory [p. 74 below]. She regarded this as evidence of a weakening of her memory, and I had to be careful not to tell her the cause of this particular instance of amnesia. – The overwhelming success of the treatment in this respect was no doubt also due to the great detail in which I had got her to repeat these memories to me (in far greater detail than is shown in my notes), whereas with other memories I was too often satisfied with a mere mention.

To my surprise, after this suggestion of mine, she began without any transition speaking of Prince L., whose escape from an asylum was being talked about a great deal at the time. She brought out new fears about asylums – that people in them were treated with douches of ice-cold water on the head and put into an apparatus which turned them round and round till they were quiet. When, three days ago, she had first complained about her fear of asylums, I had interrupted her after her first story, that the patients were tied on to chairs. I now saw that I had gained nothing by this interruption and that I cannot evade listening to her stories in every detail to the very end. After these arrears had been made up, I took this fresh crop of fears from her as well. I appealed to her good sense and told her she really ought to believe me more than the silly girl from whom she had had the gruesome stories about the way in which asylums are run. As I noticed that she still stammered occasionally in telling me these further things, I asked her once more what the stammer came from. No reply. 'Don't you know?' 'No.' 'Why not?' 'Why not? Because I *mayn't*!' (She pronounced these words violently and angrily.) This declaration seemed to me to be evidence of the success
[62] of my suggestion, but she expressed a desire for me to wake her up from her hypnosis, and I did so.[1]

May 12 [*morning*]. Contrary to my expectation, she had slept badly and only for a short time. I found her in a state of great anxiety, though, incidentally, without showing her usual physical signs of it. She would not say what the matter was, but only that she had had bad dreams and kept seeing the same things. 'How dreadful it would be', she said, 'if they were to come to life.' During the massage she dealt with a few points in reply to questions. She then became cheerful; she told me about her social life at her dower house on the Baltic,[2] of the important people whom she entertains from the neighbouring town, and so on.

Hypnosis. She had had some fearful dreams. The legs and arms of the chairs were all turned into snakes; a monster with a vulture's beak was

1 It was not until the next day that I understood this little scene. Her unruly nature, which rebelled, both in her waking state and in artificial sleep, against any constraint, had made her angry with me because I had assumed that her narrative was finished and had interrupted it by my concluding suggestion. I have come across many other proofs that she kept a critical eye upon my work in her hypnotic consciousness. She had probably wanted to reproach me with interrupting her story today just as I had previously interrupted her accounts of the horrors in the asylum; but she had not ventured to do so. Instead of this, she had produced these further stories [about asylums], apparently without any transition and without revealing the connecting thoughts. My blunder was made plain to me next day by a depreciatory comment on her part.

2 [See footnote 3, p. 46 above.]

tearing and eating at her all over her body; other wild animals leapt upon her, etc. She then passed on to other animal deliria, which, however, she qualified with the addition 'That was real' (not a dream): how (on an earlier occasion) she had been going to pick up a ball of wool, and it was a mouse and ran away; how she had been on a walk, and a big toad suddenly jumped out at her, and so on. I saw that my general prohibition had been ineffective and that I should have to take her frightening impressions away from her one by one.[1] I took an opportunity of asking her, too, why she had gastric pains and what they came [63]
from. (I believe that all her attacks of zoöpsia [animal hallucinations] are accompanied by gastric pains.) Her answer, which she gave rather grudgingly, was that she did not know. I requested her to remember by tomorrow. She then said in a definitely grumbling tone that I was not to keep on asking her where this and that came from, but to let her tell me what she had to say. I fell in with this, and she went on without preface: 'When they carried him out, I could not believe he was dead.' (So she was talking of her husband again, and I saw now that the cause of her ill-humour was that she had been suffering from the residues of this story which had been kept back.) After this, she said, she had hated her child for three years, because she always told herself that she might have been able to nurse her husband back to health if she had not been in bed on account of the child. And then after her husband's death there had been nothing but insults and agitations. His relatives, who had always been against the marriage and had then been angry because they had been so happy together, had spread a rumour that she had poisoned him, so that she had wanted to demand an inquiry.[2] Her relatives had involved her in all kinds of legal proceedings with the help of a shady journalist. The wretch had sent round agents to stir people up against her. He got the local papers to print libellous articles about her, and then sent her the cuttings. This had been the origin of her unsociability and her hatred of all strangers. After I had spoken some calming words about what she had told me, she said she felt easier.

May 13 [*morning*]. Once again she had slept badly, owing to gastric pains. She had not eaten any supper. She also complained of pains in her right arm. But she was in a good mood; she was cheerful, and, since

1 I unfortunately failed to enquire into the significance of Frau Emmy's animal visions – to distinguish, for instance, what was symbolic in her fear of animals from what was primary horror [*Grausen*], such as is characteristic of many neuropaths from youth onwards.

2 [She made an application for exhumation in order for an autopsy to be performed. When this was granted, it was revealed that the children of the first marriage, in collaboration with the police, had already had an autopsy performed. No traces of poison were found.]

yesterday, has treated me with special distinction. She asked me my opinion about all sorts of things that seemed to her important, and became quite unreasonably agitated, for instance, when I had to look for the towels needed in massage, and so on. Her clacking and facial tic were frequent.

Hypnosis. Yesterday evening it had suddenly occurred to her why the small animals she saw grew so enormous. It happened to her for the first time at D—— during a theatrical performance in which a huge lizard
[64] appeared on the stage. This memory had tormented her a great deal yesterday as well.[1]

The reason for the reappearance of the clacking was that yesterday she had abdominal pains and had tried not to show it by groaning. She knew nothing of the true precipitating cause of the clacking (see p. 49). She remembered, too, that I had instructed her to discover the origin of her gastric pains. She did not know it, however, and asked me to help her. I asked whether, perhaps, on some occasion after a great excitement, she had forced herself to eat. She confirmed this. After her husband's death she had for a long time lost her appetite completely and had only eaten from a sense of duty; and her gastric pains had in fact begun at that time. I then removed her gastric pains by stroking her a few times across the epigastrium. She then began of her own accord to talk about the things that had most affected her. 'I have told you,' she said, 'that I was not fond of the child. But I ought to add that one could not have guessed it from my behaviour. I did everything that was necessary. Even now I reproach myself for being fonder of the elder one.'

May 14 [*morning*]. She was well and cheerful and had slept till 7.30 this morning. She only complained of slight pains in the radial region of her hand and in her head and face. What she tells me before the hypnosis becomes more and more significant. Today she had scarcely anything dreadful to produce. She complained of pains and loss of sensation in her right leg. She told me that she had had an attack of abdominal inflammation in 1871; when she had hardly recovered from this, she had nursed her sick brother, and it was then that the pains first came on. They had even led to a temporary paralysis of her right leg.

1 The visual memory of the big lizard had no doubt only attained its great importance owing to its coinciding in time with a powerful affect which she must have experienced during the theatrical performance. In treating the present patient, as I have already confessed [pp. 50 *n*. and 57 *n*. 1 above], I was often content to receive the most superficial explanations. In this instance, too, I failed to make any further investigation. – We shall be reminded, moreover, of hysterical macropsia. Frau Emmy was extremely short-sighted and astigmatic, and her hallucinations may often have been provoked by the indistinctness of her visual perceptions.

During the hypnosis I asked her whether it would now be possible for her to take part in social life or whether she was still too much afraid. She said it was still disagreeable to have anyone standing behind her or just beside her. In this connection she told me of some more occasions on which she had been disagreeably surprised by someone suddenly appearing. Once, for instance, when she had been going for a walk with her daughters on the island of Rügen, two suspicious-looking individuals had come out from some bushes and insulted them. In Abbazia, while she was out for a walk one evening, a beggar had suddenly emerged from behind a rock and had knelt down in front of her. It seems that he was a harmless lunatic. Lastly, she told me of how her isolated country house had been broken into at night, which had very much alarmed her. It is easy to see, however, that the essential origin of this fear of people was the persecution to which she had been subjected after her husband's death.[1] [65]

Evening. Though she appeared to be in high spirits, she greeted me with the exclamation: 'I'm frightened to death; oh, I can hardly tell you, I hate myself!' I learnt at last that she had had a visit from Dr Breuer and that on his appearance she had given a start of alarm. As he noticed it, she had assured him that it was 'only this once'. She felt so very sorry on my account that she should have had to betray this relic of her former nervousness. I have more than once had occasion to notice during these last few days how hard she is on herself, how liable she is to blame herself severely for the least signs of neglect – if the towels for the massage are not in their usual place or if the newspaper for me to read when she is asleep is not instantly ready to hand. After the removal of the first and most superficial layer of tormenting recollections, her morally oversensitive personality, with its tendency to self-depreciation, has come into view. Both in her waking state and under hypnosis, I duly told her (what amounted to the old legal tag '*de minimis non curat lex*') that there is a whole multitude of indifferent, small things lying between what is good and what is evil – things about which no-one need reproach himself. She did not take in my lesson, I fancy, any more than would an ascetic mediaeval monk, who sees the finger of God or a temptation of the Devil in every trivial event of his life and who is incapable of picturing the world even for a brief moment or in its smallest corner as being without reference to himself. [66]

1 At the time I wrote this [i.e. 1888 or 1889; see Appendix A] I was inclined to look for a *psychical* origin for all symptoms in cases of hysteria. I should now explain this sexually abstinent woman's tendency to anxiety as being due to *neurosis* (i.e. anxiety neurosis). [See p. 78 below.]

In her hypnosis she brought up some further horrifying images (in Abbazia, for instance, she saw bloody heads on every wave of the sea). I made her repeat the lessons I had given her while she was awake.

May 15 [*morning*]. She had slept till 8.30 a.m. but had become restless towards morning, and received me with some slight signs of her tic, clacking and speech inhibition. 'I'm frightened to death,' she said once more. In reply to a question she told me that the pension in which her children were staying was on the fourth floor of a building and reached by a lift. She had insisted yesterday that the children should make use of the lift for coming down as well as going up, and was now reproaching herself about this, because the lift was not entirely to be trusted. The owner of the pension had said so himself. Had I heard, she asked, the story of the Countess Sch. who had been killed in Rome in an accident of that kind? I happen to be acquainted with the pension and I know that the lift is the private property of the owner of the pension; it does not seem to me very likely that this man, who makes a special point of the lift in an advertisement, would himself have warned anyone against using it. It seemed to me that we had here one of the paramnesias that are brought about by anxiety. I told her my view and succeeded without any difficulty in getting her herself to laugh at the improbability of her fears. For that very reason I could not believe that this was the cause of her anxiety and determined to put the question to her hypnotic consciousness. During massage, which I resumed today after a few days' interval, she told me a loosely connected string of anecdotes, which may have been true – about a toad which was found in a cellar, an eccentric mother who looked after her idiot child in a strange fashion, a woman who was shut up in an asylum because she had melancholia – and which showed the kind of recollections that passed through her head when she was in a disquieted frame of mind. When she had got these stories out she became very cheerful. She described her life on her estate and her
[67] contacts with prominent men in German Russia and North Germany; and I really found it extremely hard to reconcile activities of this kind with the picture of such a severely neurotic woman.

I therefore asked her in hypnosis why she was so restless this morning. In place of her doubts about the lift, she informed me that she had been afraid that her period was going to start again and would again interfere with the massage.[1]

1 The sequence of events had accordingly been as follows: When she woke up in the morning she found herself in an anxious mood, and to account for it she grasped at the first anxious idea that came to mind. On the previous afternoon she had had a conversation about the lift at the pension. Over-careful of her children as usual, she had asked their governess whether her elder daughter, who could not walk much on account of ovarian neuralgia on the right side and pains in the right leg, used the lift for going down as well as up. A paramnesia then enabled her to link

I then got her to tell me the history of her pains in the leg. She began in the same way as yesterday [about having nursed her brother] and then went on with a long series of instances of experiences, alternately [68]

the anxiety she was conscious of with the idea of the lift. Her consciousness did not present her with the *real* cause of her anxiety; *that* only emerged – but now it did so without any hesitation – when I questioned her about it in hypnosis. The process was the same as that studied by Bernheim and others after him in persons who carry out in a post-hypnotic condition instructions given them during hypnosis. For instance, Bernheim (1886, 29) suggested to a patient that after he woke up he should put both his thumbs in his mouth. He did so, and excused his action by saying that his tongue had been giving him pain since the previous day when he had bitten it in an epileptiform attack. Again, in obedience to a suggestion, a girl made an attempt to murder a law-court officer who was totally unknown to her. When she was seized and questioned as to the motives of her act, she invented a story of a wrong done to her which called for revenge. There seems to be a necessity for bringing psychical phenomena of which one becomes conscious into causal connection with other conscious material. In cases in which the true causation evades conscious perception one does not hesitate to attempt to make another connection, which one believes, although it is false. It is clear that a split in the content of consciousness must greatly facilitate the occurrence of 'false connections' of this kind. [See p. 269 f. below.]

I shall dwell a little on this example I have given of a false connection, since in more than one respect it deserves to be described as typical. It is typical, in the first place, of the present patient's behaviour; for in the further course of the treatment she afforded me many opportunities of resolving such false connections by explanations arrived at in hypnosis, and of removing their effects. I will give a detailed account of one of these instances, since it throws a strong light on the psychological phenomenon in question. I had recommended Frau Emmy to try replacing her usual lukewarm bath by a hip-bath of cool water, which I told her would be more refreshing. She used to obey medical instructions implicitly, but never ceased to view them with profound mistrust. I have already said that she had hardly ever derived any benefit from her medical treatment. My advice to her to take cool baths was not delivered in such an authoritative manner as to prevent her from having the courage to give open expression to her hesitations: 'Whenever I have taken a cool bath,' she said, 'it has made me melancholy for the rest of the day. But I will try it again, if you like; you mustn't think I won't do whatever you tell me to.' I pretended to give up my proposal, but in her next hypnosis I suggested to her that she should herself put forward the idea of cool baths – having thought it over, she would like to try the experiment after all, and so on. This in fact happened. Next day, she took up the idea of having cool hip-baths; she tried to convince me with all the arguments which I had previously used to her, and I agreed without much enthusiasm. But on the day after she had had the hip-bath I did in fact find her in a deep depression. 'Why are you like this today?' I asked. 'I knew beforehand that it would happen,' she answered, 'it's because of the cold bath; it always happens.' 'It was you yourself who asked for it,' I said. 'Now we know they don't suit you. We'll go back to the lukewarm ones.' Afterwards I asked her in her hypnosis, 'Was it really the cool bath that depressed you so much?' 'Oh,' was her answer, 'the cool bath had nothing to do with it. But I read in the paper this morning that a revolution had broken out in San Domingo. Whenever there is any unrest there the whites are always the sufferers; and I have a brother in San Domingo who has already caused us a lot of concern, and I am worried now in case something happens to him.' This brought to a close the issue between us. Next morning she took her cool hip-bath as though it were a matter of course and continued doing so for several weeks without ever attributing any depression to that source.

It will be agreed that this instance is typical also of the behaviour of a large number of neuropaths in regard to the therapeutic procedures recommended by their physicians. The patient who develops a symptom on a particular day – whether owing to unrest in San Domingo or elsewhere – is always inclined to attribute it to his doctor's latest advice. Of the two conditions necessary for bringing about a false connection of this kind, one, mistrust, seems always to be present; while the other, the splitting of consciousness, is replaced by the fact that most neuropaths have in part no knowledge of the true causes (or at any rate the releasing causes) of their disorder, and in part deliberately avoid such knowledge, because they are unwilling to be reminded of that share of the causes for which they themselves are to blame.

It might be thought that these psychical conditions which we have laid down for neuropaths as distinct from hysterics – namely, ignorance or deliberate overlooking – would necessarily be more favourable for the production of a false connection than would be the presence of a split in consciousness, which, after all, withdraws material for causal connections from consciousness. The split, however, is rarely a clear-cut one. As a rule, portions of the subconscious

[69] distressing and irritating, which she had had at the same time as her pains in the leg and the effect of which had each time been to make them

[cf. p. 41 *n.* 2 above] complex of ideas [*Vorstellungskomplexes*] intrude into the subject's ordinary consciousness, and it is precisely they that provoke this kind of disturbance. What is usually perceived consciously, as in the instances I have quoted above, is the general feeling attached to the complex – a mood of anxiety [*Angst*], it may be, or of grief; and it is this feeling that, by a kind of 'compulsion to associate', must have a connection found for it with some complex of ideas which is present in consciousness. (Compare, too, the mechanism of obsessional ideas, described in two papers, 1894*a* and 1895*c*.)

Not long ago I was able to convince myself of the strength of a compulsion of this kind towards association from some observations made in a different field. For several weeks I found myself obliged to exchange my usual bed for a harder one, in which I had more numerous or more vivid dreams, or in which, it may be, I was unable to reach the normal depth of sleep. In the first quarter of an hour after waking I remembered all the dreams I had had during the night, and I took the trouble to write them down and try to solve them. I succeeded in tracing all these dreams back to two factors: (1) to the necessity for working out any ideas which I had only dwelt upon cursorily during the day – which had only been touched upon and not finally dealt with; and (2) to the compulsion to link together any ideas that might be present in the same state of consciousness. The senseless and contradictory character of the dreams could be traced back to the uncontrolled ascendancy of this latter factor.

It is a quite regular thing for the mood attaching to an experience and the subject matter of that experience to come into different relations to the primary consciousness. This was shown in the case of another patient, Frau Cäcilie M., whom I got to know far more thoroughly than any of the other patients mentioned in these studies. [See Editors' Introduction, pp. xv–xvi above. The history of this very important treatment is described by Swales (1986).] I collected from her very numerous and convincing proofs of the existence of a psychical mechanism of hysterical phenomena such as I have put forward above. Personal considerations unfortunately make it impossible for me to give a detailed case history of this patient, though I shall have occasion to refer to it from time to time. Frau Cäcilie had latterly been in a peculiar hysterical state. This state was certainly not a unique one, though I do not know if it has hitherto been recognized. It might be called a 'hysterical psychosis for the payment of old debts'. The patient had experienced numerous psychical traumas and had spent many years in a chronic hysteria which was attended by a great variety of manifestations. The causes of all these states of hers were unknown to her and everyone else. Her remarkably well-stocked memory showed the most striking gaps. She herself complained that it was as though her life was chopped in pieces. One day an old memory suddenly broke in upon her clear and tangible and with all the freshness of a new sensation. For nearly three years after this she once again lived through all the traumas of her life – long forgotten, as they seemed to her, and some, indeed, never remembered at all – accompanied by the acutest suffering and by the return of all the symptoms she had ever had. The 'old debts' which were thus paid covered a period of thirty-three years and made it possible to discover the origins, often very complicated, of all her abnormal states. The only way of relieving her was to give her an opportunity of talking off under hypnosis the particular reminiscence which was tormenting her at the moment, together with all its accompanying load of feelings and their physical expression. When I was prevented from doing so, so that she was obliged to say these things to a person in whose presence she felt embarrassed, it sometimes happened that she would tell him her story quite calmly and would subsequently, in hypnosis, produce for me all the tears, all the expressions of despair, with which she would have wished to accompany her recital. For a few hours after a purgation of this kind during hypnosis she used to be quite well and on the spot. After a short interval the next reminiscence of the series would break its way in. But this reminiscence would be preceded some hours earlier by the mood which was proper to it. She would become anxious or irritable or despairing without ever suspecting that this mood did not belong to the present moment but to the state to which she would next be subject. During this transition period she would habitually make a false connection to which she would obstinately cling until her next hypnosis. For instance, she once greeted me with the question: 'Am I not a worthless person? Is it not a sign of worthlessness that I said to you what I did yesterday?' What she had actually said to me the day before did not in fact seem to me to justify this damning verdict. After a short discussion, she clearly recognized this; but her next hypnosis brought to light a recollection of an occasion, twelve years earlier, which had aroused severe self-reproaches in her – though, incidentally, she no longer subscribed to them in the least.

worse, even to the point of her having bilateral paralysis of the legs with loss of sensation in them. The same was true of the pains in her arm. They too had come on while she was nursing someone who was ill, at [70] the same time as the 'neck cramps'. Concerning the latter, I only learnt that they succeeded some curious restless states accompanied by depres- [71] sion which had been there previously. They consist in an 'icy grip' on the back of the neck, together with an onset of rigidity and a painful coldness in all her extremities, an incapacity to speak and complete prostration. They last from six to twelve hours. My attempts to show that this complex of symptoms represented a recollection failed. I put some questions to her with a view to discovering whether her brother, while she was nursing him during his delirium, had ever caught hold of her by the neck; but she denied this. She said she did not know where these attacks came from.[1]

Evening. She was in very good spirits and showed a great sense of [72] humour. She told me incidentally that the affair of the lift was not as she had reported it. The proprietor had only said what he did in order

[The last paragraph but one of this footnote gives us the earliest published report of a tentative approach by Freud to the problem of the interpretation of dreams. Both the factors which he brings forward here were given a place in his ultimate analysis, though only a secondary one. The first of them was the theory championed by Robert and was discussed in Chapter I (G) of *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 69–71, and was partly accepted by Freud in Chapter VII (D), ibid., **5**, 518. The second of the factors brought forward here can be found mentioned in Chapter V (A), ibid., **4**, 158–9.]

1 On subsequent reflection, I cannot help thinking that these 'neck cramps' may have been determined organically and have been analogous to migraine. In medical practice we come across a number of conditions of this kind which have not been described. These show such a striking resemblance to the classical attack of hemicrania that we are tempted to extend the concept of the latter and to attach only secondary importance to the localization of the pain [cf. Freud, 1895*f*; ibid., **3**]. As we know, many neuropathic women very often have hysterical attacks (spasms and deliria) along with an attack of migraine. Every time I observed a 'neck cramp' in Frau Emmy it was accompanied by an attack of delirium. [Cf. p. 85 below.]

As regards the pains in her arm and leg, I am of the opinion that what we have here is the not very interesting and correspondingly common case of determination by chance coincidence. She had pains of this kind while she was in an agitated state nursing her sick brother; and, owing to her exhaustion, she felt them more acutely than usual. These pains, which were originally associated only accidentally with those experiences, were later repeated in her memory as the somatic symbol of the whole complex of associations. I shall be able below [p. 155 ff.] to give several more examples in confirmation of this process. It seems probable that in the first instance these pains were rheumatic; that is to say, to give a definite sense to that much-misused term, they were of a kind which resides principally in the muscles, involves a marked sensitiveness to pressure and modification of consistency in the muscles, is at its most severe after a considerable period of rest and immobilization of the extremity (i.e. in the morning), is improved by practising the painful movement and can be dissipated by massage. These myogenic pains, which are universally common, acquire great importance in neuropaths. They themselves regard them as nervous and are encouraged in this by their physicians, who are not in the habit of examining muscles by digital pressure. Such pains provide the material of countless neuralgias and so-called sciaticas, etc. I will refer only briefly here to the relation of these pains to the gouty diathesis. My patient's mother and two of her sisters suffered very severely from gout (or chronic rheumatism). Some part of the pains which she complained of at the time of the treatment may, like her original pains, have been of contemporary origin. I cannot tell, since I had no experience then in forming a judgement of this state of the muscles. [See p. 80 below.]

to give an excuse for the lift not being used for downward journeys. She asked me a great many questions which had nothing pathological about them. She has had distressingly severe pains in her face, in her hand on the thumb side and in her leg. She gets stiff and has pains in her face if she sits without moving or stares at some fixed point for any considerable time. If she lifts anything heavy it brings on pains in her arm. – An examination of her right leg showed fairly good sensibility in her thigh, a high degree of anaesthesia in the lower part of the leg and in the foot and less in the region of the buttock and hip.

In hypnosis she informed me that she still occasionally has frightening ideas [*Angstvorstellungen*], such as that something might happen to her children, that they might fall ill or lose their lives, or that her brother, who is now on his honeymoon, might have an accident, or his wife might die (because the marriages of all her brothers and sisters had been so short). I could not extract any other fears [*ängstigen*] from her. I forbade her any need to be frightened when there was no reason for it. She promised to give it up 'because you ask me to'. I gave her further suggestions for her pains, her leg, etc.

May 16 [*morning*]. She had slept well. She still complained of pains in her face, arms and legs. She was very cheerful. Her hypnosis yielded nothing. I applied a faradic brush to her anaesthetic leg.

Evening. She gave a start as soon as I came in. 'I'm so glad you've come,' she said, 'I am so frightened.' At the same time she gave every indication of terror, together with stammering and tic. I first got her to tell me in her waking state what had happened. Crooking her fingers and stretching out her hands before her, she gave a vivid picture of her terror as she said: 'An enormous mouse suddenly whisked across my hand in the garden and was gone in a flash; things kept on gliding backwards and forwards.' (An illusion from the play of shadows?) 'A whole lot of mice were sitting in the trees. – Don't you hear the horses stamping in the circus? – There's a man groaning in the next room; he must be in pain after his operation. – Can I be in Rügen? Did I have a
[73] stove there like that?' She was confused by the multitude of thoughts crossing one another in her mind and by her efforts to sort out her actual surroundings from them. When I put questions to her about contemporary things, such as whether her daughters were here, she could make no answer.

I tried to disentangle the confusion of her mind under hypnosis. I asked her what it was that frightened her. She repeated the story of the

mouse with every sign of terror, and added that as she went down the steps she saw a dreadful animal lying there, which vanished at once. I said that these were hallucinations and told her not to be frightened of mice; it was only drunkards who saw them (she disliked drunkards intensely). I told her the story of Bishop Hatto.[1] She knew it too, and listened to it with extreme horror. – 'How did you come to think of the circus?' I went on to ask. She said that she had clearly heard the horses stamping in their stables nearby and getting tied up in their halters, which might injure them. When this happened Johann used to go out and untie them. I denied that there were stables nearby or that anyone in the next room had groaned. Did she know where she was? She said she knew *now*, but had thought earlier that she was in Rügen. I asked her how she got on to this memory. They had been talking in the garden, she said, of how hot it was in one part of it, and all at once the thought had come to her of the shadeless terrace in Rügen. Well then, I asked, what were her unhappy memories of her stay in Rügen? She produced a series of them. She had had the most frightful pains there in her legs and arms; when she was out on excursions there she had several times been caught in a fog and lost her way; twice, while she was on a walk, a bull had come after her, and so on. How was it that she had had this attack today? – How (she answered)? She had written a great many letters; it had taken her three hours and had given her a bad head. – I could assume, accordingly, that her attack of delirium was brought on by fatigue and that its content was determined by associations [*Anklänge*] from such things as the shadeless place in the garden, etc. I repeated all the lessons I have been in the habit of giving her and left her composed to sleep.

May 17 [*morning*]. She had a very good night. In the bran bath which she had today, she gave some screams because she took the bran for worms. I heard this from the nurse. She herself was reluctant to tell me about it. She was almost exaggeratedly cheerful, but she kept interrupting herself with cries of 'ugh!' and made faces expressive of terror. She also stammered more than she has for the last few days. She told me she had dreamt last night that she was walking on a lot of leeches. The night before she had had horrible dreams. She had had to lay out a number of dead people and put them in coffins, but would not put the lids on. (Obviously, a recollection of her husband.) She told me further that in the course of her life she had had a large number of adventures with [74]

1 [Who, according to legend, was eaten by rats.]

animals. The worst had been with a bat which had got caught in her wardrobe, so that she had rushed out of the room without any clothes on. To cure her of this fear her brother had given her a lovely brooch in the form of a bat; but she had never been able to wear it.

Under hypnosis she explained that her fear of worms came from her having once been given a present of a pretty pincushion; but next morning, when she wanted to use it, a lot of little worms had crept out of it, because it had been filled with bran which was not quite dry. (A hallucination? Perhaps a fact.) I asked her to tell me some more animal stories. Once, she said, when she had been walking with her husband in a park in St Petersburg, the whole path leading to a pond had been covered with toads, so that they had had to turn back. There had been times when she had been unable to hold out her hand to anyone, for fear of its turning into a dreadful animal, as had so often happened. I tried to free her from her fear of animals by going through them one by one and asking her if she was afraid of them. In the case of some of them she answered 'no'; in the case of others, 'I mustn't be afraid of them.'[1] I asked her why she had stammered and jerked about so much yesterday. She replied that she always did this when she was very frightened.[2] – But why *had* she been so frightened yesterday? – Because all kinds of oppressive thoughts had come into her head in the garden: in particular, how she could prevent something from heaping up again inside her after her treatment had come to an end. I repeated the three reasons for feeling reassured which I had already given her: (1) that she had become altogether healthier and more capable of resistance, (2) that she would get the habit of telling her thoughts to someone she was on close terms with, and (3) she would henceforth regard as indifferent a whole number of things which had hitherto weighed upon her. She went on to say that she had been worried as well because she had not thanked me for my visiting her late in the day; and she was afraid that I would lose patience with her on account of her recent relapse. She had been very much upset and alarmed because the

[75]

1 The procedure I was following here can scarcely be regarded as a good one: none of it was carried out exhaustively enough.

2 Her stammering and clacking were not completely relieved after they had been traced back to the two initial traumas [the occasion of her daughter's illness and the frightened horses, cf. pp. 49 and 52–3 above], though from then on the two symptoms were strikingly improved. The patient herself explained the incompleteness of the success as follows. She had got into the habit of stammering and clacking whenever she was frightened, so that in the end these symptoms had come to be attached not solely to the initial traumas but to a long chain of memories associated with them, which I had omitted to wipe out. This is a state of things which arises quite often and which always limits the beauty and completeness of the therapeutic outcome of the cathartic procedure.

house physician had asked a gentleman in the garden whether he was now able to face his operation. His wife had been sitting beside him, and she (the patient) could not help thinking that this might be the poor man's last evening. – After this last piece of information her depression seemed to be cleared up.[1]

Evening. She was very cheerful and contented. The hypnosis produced nothing whatever. I devoted myself to dealing with her muscular pains and to restoring sensibility in her right leg. This was very easily accomplished in hypnosis, but her restored sensibility was in part lost again when she woke up. Before I left her she expressed her astonishment that it was such a long time since she had had any neck cramps, though they usually came on before every thunderstorm.

May 18. She had slept last night better than she had for years. But after her bath she complained of cold at the back of her neck, tightness and [76]
pains in the face, hands and feet. Her features were strained and her hands clenched. The hypnosis brought out no psychical content underlying her neck cramp. I improved it by massage after she had woken up.[2]

1 It was here that I learnt for the first time, what was confirmed on countless later occasions, that when one is resolving a current hysterical delirium, the patient's communications are given in a reverse chronological order, beginning with the most recent and least important impressions and connections of thought and only at the end reaching the primary impression, which is in all probability the most important one causally. [The same phenomenon is mentioned by Breuer, p. 32 f. above.]

2 Her astonishment the evening before at its being so long since she had had a neck cramp was thus a premonition of an approaching condition which was already in preparation at the time and was perceived in the unconscious [cf. p. 45 *n*. 4 above]. This curious kind of premonition occurred regularly in the case already mentioned [p. 62 *n*.] of Frau Cäcilie M. If, for instance, while she was in the best of health, she said to me, 'It's a long time since I've been frightened of witches at night', or, 'how glad I am that I've not had pains in my eyes for such a long time', I could feel sure that the following night a severe onset of her fear of witches would be making extra work for her nurse or that her next attack of pains in the eyes was on the point of beginning. On each occasion what was already present as a finished product in the unconscious was beginning to show through indistinctly. This idea, which emerged as a sudden notion, was worked over by the unsuspecting 'official' consciousness (to use Charcot's term) into a feeling of satisfaction, which swiftly and invariably turned out to be unjustified.

Frau Cäcilie, who was a highly intelligent woman, to whom I am indebted for much help in gaining an understanding of hysterical symptoms, herself pointed out to me that events of this kind may have given rise to superstitions about the danger of being boastful or of anticipating evils. We must not vaunt our happiness on the one hand, nor, on the other, must we talk of the worst or it will happen. The fact is that we do not boast of our happiness until unhappiness is in the offing, and we become aware of our anticipation in the form of a boast, because in such cases the subject matter of what we are recollecting emerges before the feeling that belongs to it – that is to say, because an agreeable contrasting idea is present in consciousness. – [An allusion to this same point can be found in a footnote to a work of Freud's written some thirty years later: 'Negation' (1925*h*), *RSE*, **19**, 238 *n*. 2.]

I hope that this extract from the history of the first three weeks of the treatment will be enough to give a clear picture of the patient's state, of the character of my therapeutic efforts and of the measure of their success. I shall now proceed to amplify the case history.

The delirium which I have last described was also the last considerable disturbance in Frau Emmy von N.'s condition. Since I did not take the initiative in looking for the symptoms and their basis, but waited for something to come up in the patient or for her to tell me some thought that was causing her anxiety, her hypnoses soon ceased to produce
[77] material. I therefore made use of them principally for the purpose of giving her maxims which were to remain constantly present in her mind and to protect her from relapsing into similar conditions when she had got home. At that time I was completely under the sway of Bernheim's book on suggestion[1] and I anticipated more results from such didactic measures than I should today.[2] My patient's condition improved so rapidly that she soon assured me she had not felt so well since her husband's death. After a treatment lasting in all for seven weeks I allowed her to return to her home on the Baltic.

It was not I but Dr Breuer who received news of her about seven months later. Her health had continued good for several months but had then broken down again as a result of a fresh psychical shock. Her elder daughter, during their first stay in Vienna, had already followed her mother in developing neck cramps and mild hysterical states; but in particular, she had suffered from pains in walking owing to a retroverted uterus. On my advice she had gone for treatment to Dr N., one of our most distinguished gynaecologists, who had put her uterus right by massage, and she had remained free from trouble for several months. Her trouble recurred, however, while they were at home, and her mother called in a gynaecologist from the neighbouring university town. He prescribed a combined local and general treatment for the girl, which, however, brought on a severe nervous illness (she was seventeen at the time). It is probable that this was already an indication of her pathological disposition which was to manifest itself a year later in a character change. [See below, p. 73 f.] Her mother, who had handed the girl over to the doctors with her usual mixture of docility and mistrust, was overcome by the most violent self-reproaches after the unfortunate outcome of the treatment. A train of thought which I have not

1 [Freud himself translated this book (Bernheim, 1886), and the translation was published in 1888–89.]

2 [See, however, footnote 1, p. 89 below.]

investigated brought her to the conclusion that Dr N. and I were together responsible for the girl's illness because we had made light of her serious condition. By an act of will as it were, she undid the effects of my treatment and promptly relapsed into the states from which I had freed her. A distinguished physician in her neighbourhood, to whom she went for advice, and Dr Breuer, who was in correspondence with her, succeeded in convincing her of the innocence of the two targets of her accusations; [78] but even after this was cleared up, the aversion to me which she formed at the time was left over as a hysterical residue, and she declared that it was impossible for her to take up her treatment with me again. On the advice of the same medical authority she turned for help to a sanatorium in North Germany. At Breuer's desire I explained to the physician in charge the modifications of hypnotic therapy which I had found effective in her case.

This attempted transfer[1] failed completely. From the very first she seems to have been at cross-purposes with the doctor. She exhausted herself in resisting whatever was done for her. She went downhill, lost sleep and appetite, and only recovered after a woman friend of hers who visited her in the sanatorium in effect secretly abducted her and looked after her in her house. A short time afterwards, exactly a year after her first meeting with me, she was again in Vienna and put herself once more into my hands.

I found her much better than I had expected from the accounts I had received by letter. She could get about and was free from anxiety; much of what I had accomplished the year before was still maintained. Her chief complaint was of frequent states of confusion – 'storms in her head' as she called them. Besides this she suffered from sleeplessness, and was often in tears for hours at a time. She felt sad at one particular time of day (five o'clock). This was the regular hour at which, during the winter, she had been able to visit her daughter in the nursing home. She stammered and clacked a great deal and kept rubbing her hands together as though she was in a rage, and when I asked her if she saw a great many animals, she only replied: 'Oh keep still!'

At my first attempt to induce hypnosis she clenched her fists and exclaimed: 'I won't be given any antipyrin injections; I would rather have my pains! I don't like Dr R.; he is antipathetic to me.' I perceived that she was involved in the memory of being hypnotized in the sanatorium, and she calmed down as soon as I brought her back to the present situation.

1 [Though the German word here is '*Übertragung*', it is evidently not used in the technical sense of 'transference' which is first found at the end of this volume, on p. 269.]

[79] At the very beginning of the [resumed] treatment I had an instructive experience. I had asked her how long she had had a recurrence of the stammering, and she had hesitatingly answered (under hypnosis) that it was ever since a shock she had at D—— during the winter. A waiter at the hotel in which she was staying had concealed himself in her bedroom. In the darkness, she said, she had taken the object for an overcoat and put out her hand to take hold of it; and the man had suddenly 'shot up into the air'. I took this memory picture away, and in fact from that time on she ceased to stammer noticeably either in hypnosis or in waking life. I cannot remember what it was that led me to test the success of my suggestion, but when I returned the same evening I asked her in an apparently innocent voice how I could manage to fasten the door when I went away (while she was lying asleep) so that no-one could slip into the room. To my astonishment she gave a violent start and began grinding her teeth and rubbing her hands. She indicated that she had had a severe shock of that kind at D——, but could not be persuaded to tell me the story. I observed that she had in mind the same story which she had told me that morning during the hypnosis and which I thought I had wiped out. In her next hypnosis she told me the story in greater detail and more truthfully. In her excitement she had been walking up and down the passage and found the door of her maid's bedroom open. She had tried to go in and sit down. Her maid had stood in the way, but she refused to be stopped and walked in, and then caught sight of the dark object against the wall which turned out to be a man. It was evidently the erotic factor in this little adventure which had caused her to give an untrue account of it. This taught me that an incomplete story under hypnosis produces no therapeutic effect. I accustomed myself to regarding as incomplete any story that brought about no improvement, and I gradually came to be able to read from patients' faces whether they might not be concealing an essential part of their confessions.

The work that I had to do with her this time consisted in dealing in hypnosis with the disagreeable impressions she had received during her daughter's treatment and during her own stay in the sanatorium. She was full of suppressed anger with the physician who had compelled her under hypnosis to spell out the word 't . . . o . . . a . . . d' and she made me promise never to make her say it. In this connection I ventured upon
[80] a practical joke in one of my suggestions to her. This was the only abuse of hypnosis – and a fairly innocent one at that – of which I have to plead guilty with this patient. I assured her that her stay in the sanatorium at '*-tal*' ['-vale'] would become so remote to her that she would not even

be able to recall its name and that whenever she wanted to refer to it she would hesitate between '*-berg*' ['-hill'], '*-tal*', '*-wald*' ['-wood'] and so on. This duly happened and presently the only remaining sign of her speech inhibition was her uncertainty over this name. Eventually, following a remark by Dr Breuer, I relieved her of this compulsive paramnesia.

I had a longer struggle with what she described as 'the storms in her head' than with the residues of these experiences. When I first saw her in one of these states she was lying on the sofa with her features distorted and her whole body unceasingly restless. She kept on pressing her hands to her forehead and calling out in yearning and helpless tones the name 'Emmy', which was her elder daughter's as well as her own. Under hypnosis she informed me that this state was a repetition of the many fits of despair by which she had been overcome during her daughter's treatment, when, after she had spent hours in trying to discover some means of correcting its bad effects, no way out presented itself. When, at such a time, she felt her thoughts becoming confused, she made it a practice to call out her daughter's name, so that it might help her back to clear-headedness. For, during the period when her daughter's illness was imposing fresh duties on her and she felt that her own nervous condition was once again gaining strength over her, she had determined that whatever had to do with the girl must be kept free from confusion, however chaotic everything else in her head was.

In the course of a few weeks we were able to dispose of these memories too and Frau Emmy remained under my observation for some time longer, feeling perfectly well. At the very end of her stay something happened which I shall describe in detail, since it throws the strongest light on the patient's character and the manner in which her states came about.

I called on her one day at lunchtime and surprised her in the act of throwing something wrapped up in paper into the garden, where it was caught by the children of the house porter. In reply to my question, she admitted that it was her (dry) pudding, and that this went the same way [81] every day. This led me to investigate what remained of the other courses and I found that there was more than half left on the plates. When I asked her why she ate so little she answered that she was not in the habit of eating more and that it would be bad for her if she did; she had the same constitution as her late father, who had also been a small eater. When I enquired what she drank she told me she could only tolerate thick fluids, such as milk, coffee or cocoa; if she ever drank water or

minerals it ruined her digestion. This bore all the signs of a neurotic choice. I took a specimen of her urine and found it was highly concentrated and overcharged with urates.

I therefore thought it advisable to recommend her to drink more and decided also to increase the amount of her food. It is true that she did not look at all noticeably thin but I nevertheless thought it worthwhile to aim at feeding her up a little. When on my next visit I ordered her some alkaline water and forbade her usual way of dealing with her pudding, she showed considerable agitation. 'I'll do it because you ask me to,' she said, 'but I can tell you in advance that it will turn out badly, because it is contrary to my nature, and it was the same with my father.' When I asked her under hypnosis why it was that she could not eat more or drink any water, she answered in a rather sullen tone: 'I don't know.' Next day the nurse reported that she had eaten the whole of her helpings and had drunk a glass of the alkaline water. But I found Frau Emmy herself lying in a profoundly depressed state and in a very ungracious mood. She complained of having very violent gastric pains. 'I told you what would happen,' she said. 'We have sacrificed all the successful results that we have been struggling for so long. I've ruined my digestion, as always happens if I eat more or drink water, and I have to starve myself entirely for five days to a week before I can tolerate anything.' I assured her that there was no need to starve herself and that it was impossible to ruin one's digestion in that way: her pains were only due to the anxiety over eating and drinking. It was clear that this explanation of mine made not the slightest impression on her. For when, soon afterwards, I tried to put her to sleep, for the first time I failed to bring about hypnosis; and the furious look she cast at me convinced me that she was in open rebellion and that the situation was very grave. I gave
[82] up trying to hypnotize her, and announced that I would give her twenty-four hours to think things over and accept the view that her gastric pains came only from her fear. At the end of this time I would ask her whether she was still of the opinion that her digestion could be ruined for a week by drinking a glass of mineral water and eating a modest meal; if she said yes, I would ask her to leave. This little scene was in very sharp contrast to our normal relations, which were most friendly.

I found her twenty-four hours later, docile and submissive. When I asked her what she thought about the origin of her gastric pains, she answered, for she was incapable of prevarication: 'I think they come from my anxiety, but only because you say so.' I then put her under hypnosis and asked her once again: 'Why can't you eat more?'

The answer came promptly and consisted once more in her producing a series of chronologically arranged reasons from her store of recollections: 'I'm thinking how, when I was a child, it often happened that out of naughtiness I refused to eat my meat at dinner. My mother was very severe about this and under the threat of condign punishment I was obliged two hours later to eat the meat, which had been left standing on the same plate. The meat was quite cold by then and the fat was set so hard' (she showed her disgust) '. . . I can still see the fork in front of me . . . one of its prongs was a little bent. Whenever I sit down to a meal I see the plates before me with the cold meat and fat on them. And how, many years later, I lived with my brother who was an officer and who had that horrible disease. I knew it was contagious and was terribly afraid of making a mistake and picking up his knife and fork' (she shuddered) '. . . and in spite of that I ate my meals with him so that no-one should know that he was ill. And how, soon after that, I nursed my other brother when he had consumption so badly. We sat by the side of his bed and the spittoon always stood on the table, open' (she shuddered again) '. . . and he had a habit of spitting across the plates into the spittoon. This always made me feel so sick, but I couldn't show it, for fear of hurting his feelings. And these spittoons are still on the table whenever I have a meal and they still make me feel sick.' I naturally made a thorough clearance of this whole array of agencies of disgust and then asked why it was that she could not drink water. When she was seventeen, she replied, the family had spent some months in Munich and [83] almost all of them had contracted gastric catarrh owing to the bad drinking water. In the case of the others the trouble was quickly relieved by medical attention, but with her it had persisted. Nor had she been improved by the mineral water which she was recommended. When the doctor had prescribed it she had thought at once 'that won't be any use'. From that time onwards this intolerance both of ordinary water and mineral water had recurred on countless occasions.

The therapeutic effect of these discoveries under hypnosis was immediate and lasting. She did *not* starve herself for a week but the very next day she ate and drank without making any difficulty. Two months later she wrote in a letter: 'I am eating excellently and have put on a great deal of weight. I have already drunk forty bottles of the water. Do you think I should go on with it?'

I saw Frau von N. again in the spring of the following year at her estate near D——. At this time her elder daughter, whose name she had called out during her 'storms in the head', entered on a phase of

abnormal development. She exhibited unbridled ambitions which were out of all proportion to the poverty of her gifts, and she became disobedient and even violent towards her mother. I still enjoyed her mother's confidence and was sent for to give my opinion on the girl's condition. I formed an unfavourable impression of the psychological change that had occurred in the girl, and in arriving at a prognosis I had also to take into account the fact that all her stepbrothers and sisters (the children of Herr von N. by his first marriage) had succumbed to paranoia. In her mother's family, too, there was no lack of a neuropathic heredity, although none of her more immediate relatives had developed a chronic psychosis. I communicated to Frau von N. without any reservation the opinion for which she had asked and she received it calmly and with understanding. She had grown stout, and looked in flourishing health. She had felt relatively very well during the nine months that had passed since the end of her last treatment. She had only been disturbed by slight neck cramps and other minor ailments. During the several days which I spent in her house I came for the first time to realize the whole extent of her duties, occupations and intellectual interests. I also met
[84] the family doctor, who had not many complaints to make about the lady; so she had to some degree come to terms with the profession.

She was thus in very many respects healthier and more capable, but in spite of all my improving suggestions there had been little change in her fundamental character. She seemed not to have accepted the existence of a category of 'indifferent things'. Her inclination to torment herself was scarcely less than it had been at the time of her treatment. Nor had her hysterical disposition been quiescent during this good period. She complained, for instance, of an inability to make journeys of any length by train. This had come on during the last few months. A necessarily hurried attempt to relieve her of this difficulty resulted only in her producing a number of trivial disagreeable impressions left by some recent journeys she had made to D—— and its neighbourhood. She seemed reluctant, however, to be communicative under hypnosis, and even then I began to suspect that she was on the point of withdrawing once more from my influence and that the secret purpose of her railway inhibition was to prevent her making a fresh journey to Vienna.

It was during these days, too, that she made her complaints about gaps in her memory 'especially about the most important events' [p. 55 *n.* above], from which I concluded that the work I had done two years previously had been thoroughly effective and lasting. – One day, she was walking with me along an avenue that led from the house to an inlet in

the sea and I ventured to ask whether the path was often infested by toads. By way of reply she threw a reproachful glance at me, though unaccompanied by signs of horror; she amplified this a moment later with the words 'but the ones here are *real*'. During the hypnosis, which I induced in order to deal with her railway inhibition, she herself seemed dissatisfied with the answers she gave me, and she expressed a fear that in future she was likely to be less obedient under hypnosis than before. I determined to convince her of the contrary. I wrote a few words on a piece of paper, handed it to her and said: 'At lunch today you will pour me out a glass of red wine, just as you did yesterday. As I raise the glass to my lips you will say: "Oh, please pour me out a glass, too", and when I reach for the bottle, you will say: "No thank you, I don't think I will after all". You will then put your hand in your bag, draw out the piece of paper and find those same words written on it.' This was in the morning. A few hours later the little episode took place exactly as I had prearranged it, and so naturally that none of the many people present noticed anything. When she asked me for the wine she showed visible signs of an internal struggle – for she never drank wine – and after she had refused the drink with obvious relief, she put her hand into her bag and drew out the piece of paper on which appeared the last words she had spoken. She shook her head and stared at me in astonishment. [85]

After my visit in May, 1890, my news of Frau von N. became gradually scantier. I heard indirectly that her daughter's deplorable condition, which caused her every kind of distress and agitation, did eventually undermine her health. Finally, in the summer of 1893, I had a short note from her asking my permission for her to be hypnotized by another doctor, since she was ill again and could not come to Vienna. At first I did not understand why my permission was necessary, till I remembered that in 1890 I had, at her own request, protected her against being hypnotized by anyone else, so that there should be no danger of her being distressed by coming under the control of a doctor who was antipathetic to her, as had happened at *-berg* (*-tal*, *-wald*). I accordingly renounced my exclusive prerogative in writing.

DISCUSSION

Unless we have first come to a complete agreement upon the terminology involved, it is not easy to decide whether a particular case is to be reckoned as a hysteria or some other neurosis (I am speaking here of neuroses which are not of a purely neurasthenic type); and we have still

to await the directing hand which shall set up boundary-marks in the region of the commonly occurring mixed neuroses and which shall bring out the features essential for their characterization. If, accordingly, we are still accustomed to diagnosing a hysteria, in the narrower sense of the term, from its similarity to familiar typical cases, we shall scarcely be able to dispute the fact that the case of Frau Emmy von N. was one of hysteria. The mildness of her deliria and hallucinations (while her other mental activities remained intact), the change in her personality and store of memories when she was in a state of artificial somnambu-
[86] lism, the anaesthesia in her painful leg, certain data revealed in her anamnesis, her ovarian neuralgia, etc., admit of no doubt as to the hysterical nature of the illness, or at least of the patient. That the question can be raised at all is due only to one particular feature of the case, which also provides an opportunity for a comment that is of general validity. As we have explained in the 'Preliminary Communication' which appears at the beginning of this volume, we regard hysterical symptoms as the effects and residues of excitations which have acted upon the nervous system as traumas. Residues of this kind are not left
abführen behind if the original excitation has been discharged [*abgeführt*]^{T} by abreaction or thought activity. It is impossible any longer at this point to avoid introducing the idea of quantities (even though not measurable ones). We must regard the process as though a sum of excitation [*Erregung*]^{T} impinging on the nervous system is transformed into chronic symptoms insofar as it has not been employed for external action in proportion to its amount.[1] Now we are accustomed to find in hysteria that a considerable part of this 'sum of excitation' of the trauma is transformed into purely somatic symptoms. It is this characteristic of hysteria which has so long stood in the way of its being recognized as a psychical disorder.

If, for the sake of brevity, we adopt the term 'conversion'[2] to signify the transformation of psychical excitation into chronic somatic symptoms, which is so characteristic of hysteria, then we may say that the case of Frau Emmy von N. exhibited only a small amount of conversion. The excitation, which was originally psychical, remained for the most

1 [For a detailed account of Freud's attempt at explaining psychology on a quantitative basis, see his posthumously published 'Project for a Scientific Psychology' (1950*a*), *RSE*, **1**, written a few months after the present work. He had already expressed these views briefly in his first paper on 'The Neuropsychoses of Defence' (1894*a*), ibid., **3**, 56. See also the Editors' Introduction, p. xx ff. above.]

2 [Freud had introduced this term in his first paper on 'The Neuropsychoses of Defence' (1894*a*). See, however, p. 184 *n*. below.]

part in the psychical sphere, and it is easy to see that this gives it a resemblance to the other, non-hysterical neuroses. There are cases of hysteria in which the whole surplus of stimulation undergoes conversion, so that the somatic symptoms of hysteria intrude into what appears to be an entirely normal consciousness. An incomplete transformation is however more usual, so that some part at least of the affect that [87] accompanies the trauma persists in consciousness as a component of the subject's state of feeling.

The psychical symptoms in our present case of hysteria with very little conversion can be divided into alterations of mood (anxiety, melancholic depression), phobias and abulias (inhibitions of will). The two latter classes of psychical disturbance are regarded by the French school of psychiatrists as stigmata of neurotic degeneracy, but in our case they are seen to have been adequately determined by traumatic experiences. These phobias and abulias were for the most part of traumatic origin, as I shall show in detail.

Some of the phobias, it is true, corresponded to the primary phobias of human beings, and especially of neuropaths – in particular, for instance, her fear of animals (snakes and toads, as well as all the vermin of which Mephistopheles boasted himself master[1]), and of thunderstorms and so on. But these phobias too were established more firmly by traumatic events. Thus her fear of toads was strengthened by her experience in early childhood of having a dead toad thrown at her by one of her brothers, which led to her first attack of hysterical spasms [p. 48 above]; and similarly, her fear of thunderstorms was brought out by the shock which gave rise to her clacking [p. 53], and her fear of fogs by her walk on the island of Rügen [p. 65]. Nevertheless, in this group the primary – or, one might say, the instinctive [*instinktive*][T] – fear *Instinkt* (regarded as a psychical stigma) plays the preponderant part.

The other, more specific phobias were also accounted for by particular events. Her dread of unexpected and sudden shocks was the consequence of the terrible impression made on her by seeing her husband, when he seemed to be in the best of health, succumb to a heart attack before her eyes. Her dread of strangers, and of people in general, turned out to be derived from the time when she was being persecuted by her [husband's] family and was inclined to see one of their agents in every stranger and when it seemed to her likely that strangers knew of the things that were being spread abroad about her in writing and by

1 [The lord of rats and eke of mice,
Of flies and bed-bugs, frogs and lice.
Goethe, *Faust*, Part I, Scene 3 (Bayard Taylor's translation).]

word of mouth [p. 57 above]. Her fear of asylums and their inmates
[88] went back to a whole series of unhappy events in her family and to stories poured into her listening ears by a stupid servant girl [p. 50]. Apart from this, this phobia was supported on the one hand by the primary and instinctive [*instinktive*] horror of insanity felt by healthy people, and on the other hand by the fear, felt by her no less than by all neurotics, of going mad herself. Her highly specific fear that someone was standing behind her [p. 59] was determined by a number of terrifying experiences in her youth and later life. Since the episode in the hotel [p. 70], which was especially distressing to her because of its erotic implications, her fear of a stranger creeping into her room was greatly emphasized. Finally, her fear of being buried alive, which she shared with so many neuropaths, was entirely explained by her belief that her husband was not dead when his body was carried out – a belief which gave such moving expression to her inability to accept the fact that her life with the man she loved had come to a sudden end. In my opinion, however, all these psychical[1] factors, though they may account for the *choice* of these phobias, cannot explain their *persistence*. It is necessary, I think, to adduce a *neurotic* factor to account for this persistence – the fact that the patient had been living for years in a state of sexual abstinence.[2] Such circumstances are among the most frequent causes of a tendency to anxiety.[3]

Our patient's abulias (inhibitions of will, inability to act) admit even less than the phobias of being regarded as psychical stigmata due to a general limitation of capacity. On the contrary, the hypnotic analysis of the case made it clear that her abulias were determined by a twofold psychical mechanism – which was at bottom a single one. In the first place an abulia may simply be the consequence of a phobia. This is so when the phobia is attached to an action of the subject's own instead of to an expectation [of an external event] – for instance, in our present case, the fear of going out or of mixing with people, as compared with the fear of someone creeping into the room. Here the inhibition of will
[89] is caused by the anxiety attendant upon the performance of the action. It would be wrong to regard abulias of this kind as symptoms distinct

1 [In the first German edition only, this word reads 'physical', which was clearly a misprint.]

2 [Andersson's (1979) research reveals that the patient was far from abstinent. She had many erotic affairs, sometimes with the doctors she consulted at spas and who lived in her castle as personal physicians (*Leibärzte*). It is of course possible that these affairs only began after her treatment with Freud. See, however, pp. 90–1 below.]

3 [See Freud's contemporary paper on anxiety neuroses (1895*b*), *RSE*, **3**, 90. – In the previous sentence he is using the term 'neurotic', as he sometimes does at this period, in relation to what he later (1898*a*) termed the 'actual neuroses', ibid., **3**, 265.]

from the corresponding phobias, though it must be admitted that such phobias can exist (provided they are not too severe) without producing abulias. The second class of abulias depends on the presence of affectively toned and unresolved associations which are opposed to linking up with other associations, and particularly with any that are incompatible with them. Our patient's anorexia offers a most brilliant instance of this kind of abulia [p. 72 f. above]. She ate so little because she did not like the taste, and she could not enjoy the taste because the act of eating had from the earliest times been connected with memories of disgust whose sum of affect had never been to any degree diminished; and it is impossible to eat with disgust and pleasure at the same time. Her old-established disgust at mealtimes had persisted undiminished because she was obliged constantly to suppress it, instead of getting rid of it by reaction. In her childhood she had been forced, under threat of punishment, to eat the cold meal that disgusted her, and in her later years she had been prevented out of consideration for her brothers from expressing the affects to which she was exposed during their meals together.

At this point I may perhaps refer to a short paper in which I have tried to give a psychological explanation of hysterical paralyses (Freud, 1893*c*). I there arrived at a hypothesis that the cause of these paralyses lay in the inaccessibility to fresh associations of a group of ideas connected, let us say, with one of the extremities of the body; this associative inaccessibility depended in turn on the fact that the idea of the paralysed limb was involved in the recollection of the trauma – a recollection loaded with affect that had not been disposed of. I showed from examples from ordinary life that a cathexis[1] such as this of an idea whose affect is unresolved always involves a certain amount of associative inaccessibility and of incompatibility with new cathexes.

I have not hitherto succeeded in confirming, by means of hypnotic analysis, this theory about motor paralyses, but I can adduce Frau [90] von N.'s anorexia as proving that this mechanism is the operative one in certain abulias, and abulias are nothing other than a highly specialized – or, to use a French expression, 'systematized' – kind of psychical paralysis.

Frau von N.'s psychical situation can be characterized in all essentials by emphasizing two points. (1) The distressing affects attaching to her traumatic experiences had remained unresolved – for instance, her

1 [This seems to be the first published appearance of the term '*Besetzung*' ('cathexis') in the special sense in which Freud used it to denote one of the most fundamental concepts in his psychological theory. See the Editors' Introduction, p. xxii f. above.]

depression, her pain (about her husband's death), her resentment (at being persecuted by his relatives), her disgust (at the compulsory meals), her fear (about her many frightening experiences), and so on. (2) Her memory exhibited a lively activity which, sometimes spontaneously, sometimes in response to a contemporary stimulus (e.g. the news of the revolution in San Domingo [p. 61 *n.* above]), brought her traumas with their accompanying affects bit by bit into her present-day consciousness. My therapeutic procedure was based on the course of this activity of her memory and endeavoured day by day to resolve and get rid of whatever that particular day had brought to the surface, till the accessible stock of her pathological memories seemed to be exhausted.

These two psychical characteristics, which I regard as generally present in hysterical paroxysms, opened the way to a number of important considerations. I will, however, put off discussing them till I have given some attention to the mechanism of the somatic symptoms.

It is not possible to assign the same origin to all the somatic symptoms of these patients. On the contrary, even from this case, which was not rich in them, we find that the somatic symptoms of a hysteria can arise in a variety of ways. I will venture, in the first place, to include pains among somatic symptoms. So far as I can see, one set of Frau von N.'s pains were certainly determined organically by the slight modifications (of a rheumatic kind) in the muscles, tendons or fascia which cause so much more pain to neurotics than to normal people. Another set of pains were in all probability *memories* of pains – were mnemic symbols[1]
[91] of the times of agitation and sick-nursing which played such a large part in the patient's life. These pains, too, may well have been originally justified on organic grounds but had since then been adapted for the purposes of the neurosis. I base these assertions about Frau von N.'s pains mainly on observations made elsewhere which I shall report on a later page.[2] On this particular point little information could be gathered from the patient herself.

Some of the striking motor phenomena exhibited by Frau von N. were simply an expression of the emotions and could easily be recognized in that light. Thus, the way in which she stretched her hands in front of her with her fingers spread out and crooked expressed horror,

1 [*Erinnerungssymbol*. Cf. footnote 1, p. 63 above. Freud had already used this term in Section I of his first paper on 'The Neuropsychoses of Defence' (1894*a*), *RSE*, **3**, 46, and he repeatedly uses it in the present work. It rarely occurs in his later writings, though it is explained at some length in the first of his *Five Lectures* (1910*a*), ibid., **11**, 17–18.]

2 [The subject of rheumatic pains and their relation to hysteria is discussed at some length in the case of Fräulein Elisabeth von R. below, p. 155 f. See also above, p. 63 *n.* 1.]

and similarly her facial play. This, of course, was a more lively and uninhibited way of expressing her emotions than was usual with women of her education and race. Indeed, she herself was restrained, almost stiff in her expressive movements when she was not in a hysterical state. Others of her motor symptoms were, according to herself, directly related to her pains. She played restlessly with her fingers (1888) [p. 44 f. above] or rubbed her hands against one another (1889) [p. 69] so as to prevent herself from screaming. This reason reminds one forcibly of one of the principles laid down by Darwin to explain the expression of the emotions – the principle of the overflow of excitation [Darwin, 1872, Chap. III], which accounts, for instance, for dogs wagging their tails. We are all of us accustomed, when we are affected by painful stimuli, to replace screaming by other sorts of motor innervations. A person who has made up his mind at the dentist's to keep his head and mouth still and not to put his hand in the way may at least start drumming with his feet.[1]

A more complicated method of conversion is revealed by Frau von N.'s tic-like movements, such as clacking with the tongue and stammering, calling out the name 'Emmy' in confusional states [p. 71 above], using the composite formula 'Keep still! Don't say anything! Don't touch me!' (1888) [p. 45]. Of these motor manifestations, the stammering and clacking can be explained in accordance with a mechanism which I have described, in a short paper on the treatment of a case by hypnotic sug- [92]
gestion (1892–93*a*), as 'the putting into effect of antithetic ideas'.[2] The process, as exemplified in our present instance [p. 49 above], would be as follows. Our hysterical patient, exhausted by worry and long hours of watching by the bedside of her sick child which had at last fallen asleep, said to herself: 'Now you must be perfectly still so as not to awaken the child.' This intention probably gave rise to an antithetic idea in the form of a fear that she might make a noise all the same that would wake the child from the sleep which she had so long hoped for. Similar antithetic ideas arise in us in a marked manner when we feel uncertain whether we can carry out some important intention.

Neurotics, in whose self-feeling we seldom fail to find a strain of depression or anxious expectation, form greater numbers of these antithetic ideas than normal people, or perceive them more easily; and they regard them as of more importance. In our patient's state of exhaustion

1 [Cf. Breuer's remarks on the same topic, p. 180 below.]

2 [*Kontrastvorstellung*. The concept of antithetic ideas, as well as that of 'counterwill' (*Gegenwillen*), which is mentioned just below, was discussed in this same paper.]

the antithetic idea, which was normally rejected, proved itself the stronger. It is this idea which put itself into effect and which, to the patient's horror, actually produced the noise she dreaded. In order to explain the whole process it may further be assumed that her exhaustion was only a partial one; it affected, to use the terminology of Janet and his followers, only her 'primary' ego [*Ich*][T] and did not result in a weakening of the antithetic idea as well.

It may further be assumed that it was her horror at the noise produced against her will that made the moment a traumatic one, and fixed the noise itself as a somatic mnemic symptom[I] of the whole scene. I believe, indeed, that the character of the tic itself, consisting as it did of a succession of sounds which were convulsively emitted and separated by pauses and which could be best likened to clackings, reveals traces of the process to which it owed its origin. It appears that a conflict had occurred between her intention and the antithetic idea (the counterwill) and that this gave the tic its discontinuous character and confined the
[93] antithetic idea to paths other than the habitual ones for innervating the muscular apparatus of speech.

The patient's spastic inhibition of speech, her peculiar stammer, was the residue of an essentially similar exciting cause [pp. 52–3 above]. Here, however, it was not the *outcome* of the final innervation – the exclamation – but the process of innervation itself – the attempted convulsive inhibition of the organs of speech – which was made into a symbol of the event for her memory.

These two symptoms, the clacking and the stammering, which were thus closely related through the history of their origin, continued to be associated and were turned into chronic symptoms after being repeated on a similar occasion. Thereafter they were put to a further use. Having originated at a moment of violent fright, they were thenceforward joined to *any* fright (in accordance with the mechanism of monosymptomatic hysteria which will be described in Case 5 [p. 133 f. below]), even when the fright could not lead to an antithetic idea being put into effect.

The two symptoms were eventually linked up with so many traumas, had so much reason for being reproduced in memory, that they perpetually interrupted the patient's speech for no particular cause, in

1 ['*Symptom*' in all the German editions. It seems probable that this is a misprint for '*Symbol*'. 'Mnemic symbol' appears to give the better sense and is the term used throughout the book. (See footnote 1, p. 80 above.)]

the manner of a meaningless tic.[1] Hypnotic analysis, however, was able to demonstrate how much meaning lay concealed behind this apparent tic; and if the Breuer procedure did not succeed in this case in getting rid of the two symptoms completely at a single blow, that was because the catharsis had extended only to the three principal traumas and not to the secondarily associated ones.[2]

1 [Scarcely any references to tic occur in Freud's later writings. In a paper on the subject, Ferenczi (1921*a*) writes: 'Professor Freud, whom I had occasion to question on the meaning and significance of tic, suggested that some organic factor might be at work in it.']

2 I may here be giving an impression of laying too much emphasis on the details of the symptoms and of becoming lost in an unnecessary maze of sign-reading. But I have come to learn that the determination of hysterical symptoms does in fact extend to their subtlest manifestations and that it is difficult to attribute too much sense to them. Let me give an example to justify this statement. Some months ago I had under my treatment an eighteen-year-old girl belonging to a family with a bad heredity. Hysteria played its full part in her complex neurosis. The first thing I heard from her was a complaint that she suffered from attacks of despair of two varieties. In one variety she felt drawing and pricking sensations in the lower part of her face, from her cheeks down towards her mouth; in the other variety the toes of both her feet were stretched out convulsively and kept on wriggling about. To begin with I myself was unwilling to attach much importance to these details, and there can be no doubt that earlier students of hysteria would have been inclined to regard these phenomena as evidence of the stimulation of cortical centres during a hysterical attack. It is true that we are ignorant of the locality of the centres for paraesthesias of this kind, but it is well known that such paraesthesias usher in partial epilepsy and constitute Charcot's sensory epilepsy. Symmetrical cortical areas in the immediate vicinity of the median fissure might be held responsible for the movement of the toes. But the explanation turned out to be a different one. When I had come to know the girl better I put a straight question to her as to what kind of thoughts came to her during these attacks. I told her not to be embarrassed and said that she must be able to give an explanation of the two phenomena. The patient turned red with shame, but I was able to persuade her in the end, without using hypnosis, to give the following account, the truth of which was fully confirmed by her companion, who was present at the time. From the time when her periods first set in she had suffered for years from *cephalalgia adolescentium* which had made any regular occupation impossible and had interfered with her education. When at last she was freed from this disability, this ambitious and rather simple-minded child was determined to work extremely hard at her own improvement, so as to catch up once more with her sisters and contemporaries. In doing so she made quite unreasonable efforts, and an effort of this kind usually ended in an outburst of despair at having overestimated her powers. She also, of course, compared herself with other girls physically and felt unhappy when she discovered some physical disadvantage in herself. Her teeth projected noticeably, and she began to feel upset about this. She got the idea of correcting the defect by practising for a quarter of an hour at a time pulling down her upper lip over the projecting teeth. The failure of these childish efforts once led to a fit of despair; and thenceforward the drawing and pricking sensations from the cheek downwards were established as the content of one of her two varieties of attack. The origin of the other variety – with its motor symptoms of stretching out and wriggling the toes – was no less easily found. I was told that her first attack of this kind followed after an excursion on the Schafberg near Ischl [in Upper Austria], and her relatives were naturally inclined to set it down to overexertion. But the girl herself told me a different story. It seems that it was a favourite habit of the sisters to tease one another about the large size of their feet – an undeniable fact. The patient had long felt unhappy over this blemish and tried to force her feet into the tightest possible boots. Her observant father, however, would not allow this and saw to it that she only wore comfortably fitting footwear. She was much dissatisfied with this regulation. She thought about it all the time and acquired the habit of wriggling her toes about in her shoes, as people do when they want to discover whether a shoe is much too large, how much smaller a size they could take, etc. During the excursion on the Schafberg (which she was far from finding an exertion) there was once again, of course, an opportunity for her attention to be drawn to the subject of shoes, in view of the shortened skirts she wore. One of her sisters

[94] In accordance with the rules governing hysterical attacks, the exclamation of 'Emmy' during her attacks of confusion reproduced, it will be remembered, her frequent states of helplessness during her daughter's treatment. This exclamation was linked to the content of the attack by a complex train of thought and was in the nature of a protective formula against the attack. The exclamation would probably, through a more extended application of its meaning, have degenerated into a tic, as had in fact already happened in the case of the complicated protective formula 'Don't touch me', etc. In both these instances hypnotic treatment prevented any further development of the symptoms; but the exclam-
[95] ation 'Emmy' had only just come into existence, and I caught it while it was still on its native soil, restricted to attacks of confusion.

As we have seen, these motor symptoms originated in various ways: by putting an antithetic idea into effect (as in the clacking), by a simple conversion of psychical excitation into motor activity (as in the stammering), or by a voluntary action during a hysterical paroxysm (as in the protective measures exemplified by the exclamation 'Emmy' and the longer formula). But however these motor symptoms may have originated, they all have one thing in common. They can be shown to have an original or long-standing connection with traumas, and stand as symbols for them in the activities of the memory.

[96] Others of the patient's somatic symptoms were not of a hysterical nature at all. This is true, for example, of the neck cramps, which I regard as a modified form of migraine [p. *63 n.* 1 above] and which as such are not to be classed as a neurosis but as an organic disorder. Hysterical symptoms, however, regularly become attached to these. Frau von N.'s neck cramps, for instance, were employed for the purpose of hysterical attacks, whereas she did not have the typical symptomatology of hysterical attacks at her disposal.

I will amplify this description of Frau von N.'s psychical state by considering the pathological changes of consciousness which could be

said to her in the course of the walk: 'You've put extra big shoes on today.' She experimented by wriggling her toes and got the same impression. Thenceforward she could not escape from her agitation about the unlucky size of her feet, and when they got back from the walk her first attack came on; her toes curled up and moved about involuntarily as a mnemic symbol of the whole depressing train of thought.

I may point out that what we are dealing with here are attacks and not chronic symptoms. I may also add that after the patient's confession her first variety of symptoms ceased, but the second variety – her attacks of wriggling her toes – persisted. There must therefore have been something left over, which she had not confessed.

Postscript [in all editions]. I learnt later that the reason why the foolish girl worked so hard at beautifying herself was that she wanted to attract a young cousin of hers. – [*Added* 1924:] Some years later her neurosis turned into a dementia praecox.

observed in her. Like her neck cramps, distressing present-day events (cf. her last delirium in the garden [p. 65 above]) or anything which powerfully recalled any of her traumas brought her into a state of delirium. In such states – and the few observations I made led me to no other conclusion – there was a limitation of consciousness and a compulsion to associate similar to that prevailing in dreams [p. 62 *n.*]; hallucinations and illusions were facilitated to the highest degree and feeble-minded or even nonsensical inferences were made. This state, which was comparable to one of hallucinatory alienation, probably represented an attack. It might be regarded as an acute psychosis (serving as the equivalent of an attack) which would be classified as a condition of 'hallucinatory confusion'. A further resemblance between such states of hers and a typical hysterical attack was shown by the fact that a portion of the old-established traumatic memories could usually be detected underlying the delirium. The transition from a normal state to a delirium often occurred quite imperceptibly. She would be talking quite rationally at one moment about matters of small emotional importance, and as her conversation passed on to ideas of a distressing kind I would notice, from her exaggerated gestures or the appearance of her regular formulas of speech, etc., that she was in a state of delirium. At the beginning of the treatment the delirium lasted all day long; so that it was difficult to decide with certainty whether any given symptoms – like her gestures – formed part of her psychical state merely as symptoms of an attack, or whether – like the clacking and stammering – they had become genuine chronic symptoms. It was often only possible *after the event* [*nachträglich*][T] to distinguish between what had happened in a delirium and what had happened in her normal state. For the two states were separated in her memory, and she would sometimes be highly astonished to hear of the things which the delirium had introduced piecemeal into her normal conversation. My very first interview with her was the most remarkable instance of the way in which the two states were interwoven without paying any attention to each other. Only at one moment of this psychical seesawing did it happen that her normal consciousness, in touch with the present day, was affected. This was when she gave me an answer which originated from her delirium and said she was 'a woman dating from last century' [p. 47 *n.* 2 above].

Nachträglichkeit [97]

The analysis of these states of delirium in Frau von N. was not exhaustively carried out. This was mainly because her condition improved so rapidly that the deliria became sharply differentiated from her normal life and were restricted to the periods of her neck cramps. On the other

hand, I gathered a great deal of information about the patient's behaviour in a third state, that of artificial somnambulism. Whereas in her normal state she had no knowledge of the psychical experiences during her deliria and during her somnambulism, she had access during somnambulism to the memories of all three states. In point of fact, therefore, she was at her most normal in the state of somnambulism. Indeed, if I leave on one side the fact that in somnambulism she was far less reserved with me than she was at her best moments in ordinary life – that is, that in somnambulism she gave me information about her family and such things, while at other times she treated me as a stranger – and if, further, I disregard the fact that she exhibited the full degree of suggestibility characteristic of somnambulism, I am bound to say that during her somnambulism she was in a completely normal state. It was interesting to notice that on the other hand her somnambulism showed no trace of being supernormal, but was subject to all the mental failings that we are accustomed to associate with a normal state of consciousness.

The examples which follow throw light on the behaviour of her memory in somnambulism. In conversation one day she expressed her delight at the beauty of a plant in a pot which decorated the entrance hall of the nursing home. 'But what is its name, doctor? Do you know? I used to know its German and its Latin names, but I've forgotten them both.' She
[98] had a wide knowledge of plants, while I was obliged on this occasion to admit my lack of botanical education. A few minutes later I asked her under hypnosis if she now knew the name of the plant in the hall. Without any hesitation she replied: 'The German name is "*Türkenlilie*" [Turk's cap lily]; I really *have* forgotten the Latin one [*Lilium martagon*].' Another time, when she was feeling in good health, she told me of a visit she had paid to the Roman catacombs, but could not recall two technical terms; nor could I help her with them. Immediately afterwards I asked her under hypnosis which words she had in mind. But she did not know them in hypnosis either. So I said to her: 'Don't bother about them any more now, but when you are in the garden tomorrow between five and six in the afternoon – nearer six than five – they will suddenly occur to you.' Next evening, while we were talking about something which had no connection with catacombs, she suddenly burst out. '"Crypt", doctor, and "Columbarium".' 'Ah! those are the words you couldn't think of yesterday. When did they occur to you?' 'In the garden this afternoon just before I went up to my room.' I saw that she wanted to let me know in this way that she had followed my instructions as to time exactly, as she was in the habit of leaving the garden at about six o'clock.

Thus we see that even in somnambulism she did not have access to the whole extent of her knowledge. Even in that state there was an actual and a potential consciousness. It used often to happen that when I asked her during her somnambulism where this or that phenomenon was derived from, she would wrinkle her forehead, and after a pause would answer in a deprecatory tone: 'I don't know.' On such occasions, I had made it my practice to say: 'Think a moment; it will come to mind directly'; and after a short reflection she would be able to give me the desired information. But it sometimes happened that nothing came to her mind and that I was obliged to leave her with the task of remembering it by the next day; and this never failed to occur.

In her ordinary life Frau von N. scrupulously avoided any untruthfulness, nor did she ever lie to me under hypnosis. Occasionally, however, she would give me incomplete answers and keep back part of her story until I insisted a second time on her completing it. It was usually – as in the instance quoted on p. 70 [above] – the distaste inspired by the topic which closed her mouth in somnambulism no less than in ordinary life. [99] Nevertheless, in spite of these restrictive traits, the impression made by her mental behaviour during somnambulism was, on the whole, one of an uninhibited unfolding of her mental powers and of a full command over her store of memories.

Though it cannot be denied that in a state of somnambulism she was highly suggestible, she was far from exhibiting a pathological absence of resistance. It can be asserted on the whole that I did not make more impression on her in that state than I might have expected to do if I were making an investigation of this kind into the psychical mechanisms of someone in full possession of his faculties who put complete confidence in what I said. The only difference was that Frau von N. was unable, in what passed as her normal state, to meet me with any such favourable mental attitude. If, as with her animal phobia, I failed to give her convincing reasons, or did not go into the psychical history of the origin of a symptom but tried to operate by the agency of authoritative suggestion, I invariably observed a strained and dissatisfied expression on her face; and when, at the end of the hypnosis, I asked her whether she would still be afraid of the animal, she would answer: 'No – since you insist.' A promise like this, based only on her obedience to me, never met with any success, any more than did the many general injunctions which I laid upon her, instead of which I might just as well have repeated the single suggestion that she should get well.

But this same person who clung so obstinately to her symptoms in the

face of suggestion and would only abandon them in response to psychical analysis or personal conviction was on the other hand as amenable as the best medium to be found in any hospital, so far as irrelevant suggestions were concerned – so far as it was a question of matters not connected with her illness. I have given instances of her post-hypnotic obedience in the course of the case history. There does not seem to me to be anything contradictory in this behaviour. Here, too, the stronger idea was bound to assert itself. If we go into the mechanism of '*idées fixes*', we find that they are based upon and supported by so many experiences operating with such intensity that we cannot be surprised to find that these ideas are able to put up a successful resistance against the opposing idea brought forward by suggestion, which is clothed with
[100] only limited powers. It would have to be a truly pathological brain from which it was possible to blow away by mere suggestion such well-founded products of intense psychical events.[1]

1 I have been deeply impressed in another of my patients by this interesting contrast during somnambulism between a most far-reaching obedience in everything unconnected with the symptoms and the obstinacy with which those symptoms persist because they are deeply rooted and inaccessible to analysis. A lively and gifted girl, who had suffered for eighteen months from severe disturbances of her power of walking, was under my treatment for more than five months without my being able to help her. She was analgesic and had painful areas in both legs and a rapid tremor in her hands. She walked bent forward, dragging her legs and with short steps; she staggered as though she was a cerebellar case and, indeed, often fell down. Her temperament was strikingly cheerful. One of the leading authorities in Vienna at the time was misled by this syndrome into diagnosing her case as one of multiple sclerosis. Another specialist recognized her as a hysteric – a diagnosis which was supported by the complicated picture presented by the disease in its beginnings (pains, fainting fits, amaurosis) – and handed her on to me for treatment. I tried to improve her gait by suggestion, manipulation of her legs under hypnosis, etc., but I had no success in spite of her being an excellent subject for somnambulism. One day, after she once more came tottering into the room, one arm supported on her father's, the other on an umbrella whose tip was already much worn down, I lost patience and shouted at her in her hypnosis: 'This has gone on too long. Tomorrow morning that umbrella of yours will break in your hands and you'll have to walk without it, and from that time on you will never need an umbrella again.' I cannot imagine how I came to be so foolish as to give a suggestion to an umbrella. Afterwards I felt ashamed of myself, and did not suspect that my clever patient would save my reputation in the eyes of her father, who was a physician and was present during her hypnoses. Next day her father said to me: 'What do you think she did yesterday? We were walking along the Ringstrasse [the main boulevard in Vienna] when she suddenly got into the highest spirits. She began singing – in the very middle of the street – "Ein freies Leben führen wir" ['We live a free life', from the popularly sung robbers' chorus in Schiller's play *Die Räuber*] and beat time on the pavement with her umbrella and broke it.' Of course she herself had no notion that she had wittily transformed a nonsensical suggestion into a brilliantly successful one. Since her condition was not improved by assurances, commands and treatment under hypnosis, I turned to psychical analysis and requested her to tell me what emotion had preceded the onset of her illness. She answered (under hypnosis but without any signs of feeling) that a short time previously a young relative of hers to whom she had for many years considered herself engaged had died. This piece of information, however, produced no alteration whatever in her condition. Accordingly, during her next hypnosis, I told her I was quite convinced that her cousin's death had had nothing at all to do with her state, but that something else had happened which she had not mentioned. At this she gave way to the extent of letting fall a single significant phrase; but

It was while I was studying Frau von N.'s abulias that I began for the first time to have grave doubts about the validity of Bernheim's assertion, '*tout est dans la suggestion*' ['suggestion is everything'] and about his clever friend Delboeuf's inference: '*Comme quoi il n'y a pas d'hypnotisme*' ['That being so, there is no such thing as hypnotism'].[1] And to this day I cannot understand how it can be supposed that by merely holding up a finger and saying once 'go to sleep' I had created in the patient the peculiar psychical state in which her memory had access to all her psychical experiences. I may have *called up* the state by my suggestion but I did not *create* it, since its features – which are, incidentally, found universally – came as such a surprise to me. [101]

The case history makes sufficiently plain the way in which therapeutic work was carried out during somnambulism. As is the usual practice in hypnotic psychotherapy, I fought against the patient's pathological ideas by means of assurances and prohibitions, and by putting forward opposing ideas of every sort. But I did not content myself with this. I investigated the genesis of the individual symptoms so as to be able to combat the premises on which the pathological ideas were erected. In the course of such an analysis it habitually happened that the patient gave verbal utterance with the most violent agitation to matters whose accompanying affect had hitherto only found outlet as an expression of emotion. [Cf. p. 81 above.] I cannot say how much of the therapeutic success each time was due to my suggesting the symptom away *in statu nascendi* and how much to my resolving the affect by abreaction, since I combined both these therapeutic factors. Accordingly, this case cannot strictly be used as evidence for the therapeutic efficacy of the cathartic procedure; at the same time I must add that only those symptoms of which I carried out a psychical analysis were really permanently removed.

The therapeutic success on the whole was considerable; but it was not a lasting one. The patient's tendency to fall ill in a similar way under the impact of fresh traumas was not got rid of. Anyone who wanted to undertake the definitive cure of a case of hysteria such as this would [102]

she had hardly said a word before she stopped, and her old father, who was sitting behind her, began to sob bitterly. Naturally I pressed my investigation no further; but I never saw the patient again.

1 [Freud wrote to Emmy von N.'s elder daughter in 1918: 'It was this very case and its outcome which led me to recognize the senselessness and futility of treatment by hypnosis, and supplied the impetus to create the more reasonable therapy of psychoanalysis.' Later, in 1935, he went further and conceded to her that he had made 'a bad diagnostic error' in failing to recognize Emmy von N.'s unconscious hatred of her two children (see Tögel, 1999). Cf. Freud's footnote on pp. 92–3 below.]

have to enter more thoroughly into the complex of phenomena than I attempted to do. Frau von N. was undoubtedly a personality with a severe neuropathic heredity. It seems likely that there can be no hysteria apart from a disposition of this kind. But on the other hand disposition alone does not make hysteria. There must be reasons that bring it about, and, in my opinion, these reasons must be appropriate: the aetiology is of a specific character. I have already mentioned that in Frau von N. the affects of a great number of traumatic experiences had been retained and that the lively activity of her memory brought now one and now another of these traumas to the surface of her mind. I shall now venture to put forward an explanation of the reason why she retained the affects in this way. That reason, it is true, was connected with her hereditary disposition. For, on the one hand, her feelings were very intense; she was of a vehement nature, capable of the strongest passions[t]. On the other hand, since her husband's death, she had lived in complete mental solitude; her persecution by her relatives had made her suspicious of friends and she was jealously on guard against anyone acquiring too much influence over her actions. The circle of her duties was very wide, and she performed the whole of the mental work which they imposed on her by herself, without a friend or confidant, almost isolated from her family and handicapped by her conscientiousness, her tendency to tormenting herself and often, too, by the natural helplessness of a woman. In short the mechanism of the *retention of large sums of excitation*, apart from everything else, cannot be overlooked in this case. It was based partly on the circumstances of her life and partly on her natural disposition. Her dislike, for instance, of saying anything about herself was so great that, as I noticed to my astonishment in 1891, none of the daily visitors to her house recognized that she was ill or were aware that I was her doctor.

Does this exhaust the aetiology of this case of hysteria? I do not think so. For at the time of her two treatments I had not yet raised in my own mind the questions which must be answered before an exhaustive explanation of such a case is possible. I am now of the opinion that there must have been some added factor to provoke the outbreak of illness precisely in these last years, considering that operative aetiological conditions had been present for many years previously. It has also struck [103] me that among all the intimate information given me by the patient there was a complete absence of the sexual element, which is, after all, more liable than any other to provide occasion for traumas. It is impossible that her excitations in this field can have left no traces whatever;

what I was allowed to hear was no doubt an *editio in usum delphini* [a bowdlerized edition][1] of her life story [cf. p. 78 *n*. 2 above]. The patient behaved with the greatest and to all appearances with the most unforced sense of propriety, without a trace of prudishness. When, however, I reflect on the reserve with which she told me under hypnosis about her maid's little adventure in the hotel, I cannot help suspecting that this woman who was so passionate and so capable of strong feelings had not won her victory over her sexual needs without severe struggles, and that at times her attempts at suppressing this most powerful of all drives [*Triebe*][T] had exposed her to severe mental exhaustion. She once admitted to me that she had not married again because, in view of her large fortune, she could not credit the disinterestedness of her suitors and because she would have reproached herself for damaging the prospects of her two children by a new marriage.[2]

I must make one further remark before bringing Frau von N.'s case history to a close. Dr Breuer and I knew her pretty well and for a fairly long time, and we used to smile when we compared her character with the picture of the hysterical psyche which can be traced from early times through the writings and the opinions of medical men. We had learnt[3] from our observations on Frau Cäcilie M. that hysteria of the severest type can exist in conjunction with gifts of the richest and most original kind – a conclusion which is, in any case, made plain beyond a doubt in the biographies of women eminent in history and literature. In the same way Frau Emmy von N. gave us an example of how hysteria is compatible with an unblemished character and a well-governed mode of life. The woman we came to know was an admirable one. The moral seriousness with which she viewed her duties, her intelligence and energy, which were no less than a man's, and her high degree of education and love of truth impressed both of us greatly; while her benevolent care for the welfare of all her dependants, her humility of mind and the refinement of her manners revealed her qualities as a true lady as well. To [104]
describe such a woman as a 'degenerate' would be to distort the meaning of that word out of all recognition. We should do well to distinguish between the concepts of 'disposition' and 'degeneracy' as applied to people; otherwise we shall find ourselves forced to admit that humanity

1 ['For the use of the Dauphin' – an edition of the Classics prepared by order of Louis XIV for his son.]

2 [In the last years of her life she was swindled by a young suitor. This provoked a near-psychotic reaction.]

3 [See Editors' Introduction, p. xv *n*. 2 above.]

owes a large proportion of its great achievements to the efforts of 'degenerates'.

I must confess, too, that I can see no sign in Frau von N.'s history of the 'psychical inefficiency'[1] to which Janet attributes the genesis of hysteria. According to him, the hysterical disposition consists in an abnormal restriction of the field of consciousness (due to hereditary degeneracy) which results in a disregard of whole groups of ideas and, later, to a disintegration of the ego and the organization of secondary personalities. If this were so, what remains of the ego after the withdrawal of the hysterically organized psychical groups would necessarily also be less efficient than a normal ego; and in fact, according to Janet, the ego in hysteria is afflicted by psychical stigmata, condemned to mono-ideism and incapable of the volitional acts of ordinary life. Janet, I think, has made the mistake here of promoting what are after-effects [*Folgezustände*] of changes in consciousness due to hysteria to the rank of primary determinants of hysteria. The subject is one that deserves further consideration elsewhere;[2] but in Frau von N. there was no sign of any such inefficiency. During the times of her worst states she was and remained capable of playing her part in the management of a large industrial business, of keeping a constant eye on the education of her children, of carrying on her correspondence with prominent people in the intellectual world – in short, of fulfilling her obligations well enough for the fact of her illness to remain concealed. I am inclined to believe, then, that all this involved a considerable excess of efficiency, which could perhaps not be kept up in the long run and was bound to lead to exhaustion – to a secondary '*misère psychologique*' ['psychological impoverishment']. It seems likely that disturbances of this kind in her
[105] efficiency were beginning to make themselves felt at the time when I first saw her; but however that may be, severe hysteria had been present for many years before the appearance of the symptoms of exhaustion.[3]

1 [This passage seems to be based mainly on Janet, 1894, 300. (See footnote, p. 205 below.) The German phrase '*psychische Minderleistung*', here translated as 'psychical inefficiency', is evidently Freud's version of Janet's '*insuffisance psychologique*'.]

2 [It is discussed below by Breuer on p. 205 ff.]

3 [*Footnote added* 1924:] I am aware that no analyst can read this case history today without a smile of pity. But it should be borne in mind that this was the first case in which I employed the cathartic procedure to a large extent. [Cf. p. 44 above.] For this reason I shall leave the report in its original form. I shall not bring forward any of the criticisms which can so easily be made on it today, nor shall I attempt to fill in any of the numerous gaps in it. I will add only two things: what I afterwards discovered about the immediate [*aktuelle*] aetiology of the illness and what I heard of its subsequent course.

When, as I have mentioned, I spent a few days as Frau Emmy's guest in her country house, there was a stranger present at one of the meals who clearly tried to make himself agreeable. After his departure my hostess asked me how I had liked him and added as it were in passing: 'Only imagine, the man wants to marry me!' When I took this in connection with some other remarks which she had made, but to which I had not paid sufficient attention, I was led to conclude that she was longing at that time to be married again but found an obstacle to the realization of her purpose in the existence of her two daughters, who were the heiresses to their father's fortune.

A few years later at a Scientific Congress I met a prominent physician from Frau Emmy's part of the country [August Forel]. I asked him if he was acquainted with the lady and knew anything of her condition. Yes, he said, he knew her, and had himself given her hypnotic treatment. She had gone through the same performance with him – and with many other doctors – as she had with me. Her condition had become very bad; she had rewarded his hypnotic treatment of her by making a remarkable recovery, but had then suddenly quarrelled with him, left him, and once more set her illness going to its full extent. It was a genuine instance of the 'compulsion to repeat'.

It was not for another quarter of a century that I once more had news of Frau Emmy. Her elder daughter – the one of whom I had earlier made such an unfavourable prognosis – approached me with a request for a report on her mother's mental condition on the strength of my former treatment of her. She was intending to take legal proceedings against her mother, whom she represented as a cruel and ruthless tyrant. It seems that she had broken off relations with both her children and refused to assist them in their financial difficulties. The daughter who wrote to me had obtained a [medical] doctor's degree and was married.

[Freud's reply to this request is published in Andersson (1979, 14–15).]

CASE 3
MISS LUCY R., AGE 30 (*FREUD*)

[106] At the end of the year 1892 a colleague of my acquaintance[1] referred a young lady to me who was being treated by him for chronically recurrent suppurative rhinitis. It subsequently turned out that the obstinate persistence of her trouble was due to caries of the ethmoid bone. Latterly she had complained of some new symptoms which the well-informed physician was no longer able to attribute to a local affection. She had entirely lost her sense of smell and was almost continuously pursued by one or two subjective olfactory sensations. She found these most distressing. She was, moreover, in low spirits and fatigued, and she complained of heaviness in the head, diminished appetite and loss of efficiency.

The young lady, who was living as a governess in the house of the managing director of a factory in outer Vienna, came to visit me from time to time in my consulting hours. She was an Englishwoman.[2] She had a delicate constitution, with a poor pigmentation, but was in good health apart from her nasal affection. Her first statements confirmed what the physician had told me. She was suffering from depression and fatigue and was tormented by subjective sensations of smell. As regards hysterical symptoms, she showed a fairly definite general analgesia, with no loss of tactile sensibility, and a rough examination (with the hand) revealed no restriction of the visual field. The interior of her nose was completely analgesic and without reflexes; she was sensitive to tactile pressure there, but the perception proper to it as a sense organ was absent, alike for specific stimuli and for others (e.g. ammonia or acetic acid). The purulent nasal catarrh was just then in a phase of improvement.

In our first attempts at making the illness intelligible it was necessary to interpret the subjective olfactory sensations, since they were recurrent hallucinations, as chronic hysterical symptoms.[3] Her depression might perhaps be the affect attaching to the trauma, and it should be possible to find an experience in which these smells, which had now become subjective, had been objective. This experience must have been the trauma
[107] which the recurring sensations of smell symbolized in memory. It might

1 [Probably Wilhelm Fliess.]

2 [She was possibly Scottish (cf. p. 101 below). Freud, like most of his countrymen, hardly distinguished between 'British' and 'English'.]

3 [The diagnosis of hysteria in this case, like all the others in these *Studies*, has been questioned. (See Editors' footnote 1, p. 20 above.)]

be more correct to regard the recurrent olfactory hallucinations, together with the depression which accompanied them, as equivalents of a hysterical *attack*. The nature of recurrent hallucinations makes them unsuitable in point of fact for playing the part of *chronic* symptoms. But this question did not really arise in a case like this which showed only a rudimentary development. It was essential, however, that the subjective sensations of smell should have had a specialized origin of a sort which would admit of their being derived from some quite particular real object.

This expectation was promptly fulfilled. When I asked her what the smell was by which she was most constantly troubled she answered: 'A smell of burnt pudding.' Thus I only needed to assume that a smell of burnt pudding had actually occurred in the experience which had operated as a trauma. It is very unusual, no doubt, for olfactory sensations to be chosen as mnemic symbols of traumas, but it was not difficult to account for this choice. The patient was suffering from suppurative rhinitis and consequently her attention was especially focused on her nose and nasal sensations. What I knew of the circumstances of the patient's life was limited to the fact that the two children whom she was looking after had no mother; she had died some years earlier of an acute illness.

I therefore decided to make the smell of burnt pudding the starting point of the analysis. I will describe the course of this analysis as it might have taken place under favourable conditions. In fact, what should have been a single session spread over several. This was because the patient could visit me only in my consulting hours, when I could devote only a short time to her. Moreover, a single discussion of this sort used to extend over more than a week, since her duties would not allow her to make the long journey from the factory to my house very often. We used therefore to break our conversation off short and take up the thread at the same place next time.

Miss Lucy R. did not fall into a state of somnambulism when I tried to hypnotize her. I therefore did without somnambulism and conducted her whole analysis while she was in a state which may in fact have differed very little from a normal one.

I shall have to go into this point of my technical procedure in greater [108]
detail. When, in 1889, I visited the Nancy clinics, I heard Dr Liébeault, the doyen of hypnotism, say: 'If only we had the means of putting every patient into a state of somnambulism, hypnotic therapy would be the most powerful of all.' In Bernheim's clinic it almost seemed as though

such an art really existed and as though it might be possible to learn it from Bernheim. But as soon as I tried to practise this art on my own patients, I discovered that *my* powers at least were subject to severe limits, and that if somnambulism were not brought about in a patient at the first three attempts I had no means of inducing it. The percentage of cases amenable to somnambulism was very much lower in my experience than what Bernheim reported.

I was accordingly faced with the choice of either abandoning the cathartic method in most of the cases which might have been suitable for it, or of venturing on the experiment of employing that method without somnambulism and where the hypnotic influence was light or even where its existence was doubtful. It seemed to me a matter of indifference what degree of hypnosis – according to one or other of the scales that have been proposed for measuring it – was reached by this non-somnambulistic state; for, as we know, each of the various forms taken by suggestibility is in any case independent of the others, and the bringing about of catalepsy, automatic movements, and so on, does not work either for or against what I required for my purposes, namely that the awakening of forgotten memories should be made easier. Moreover, I soon dropped the practice of making tests to show the degree of hypnosis reached, since in quite a number of cases this roused the patients' resistance and shook their confidence in me, which I needed for carrying out the more important psychical work. Furthermore, I soon began to tire of issuing assurances and commands such as: 'You are going to sleep! . . . sleep!' and of hearing the patient, as so often happened when the degree of hypnosis was light, remonstrate with me: 'But, doctor, I'm *not* asleep', and of then having to make highly ticklish distinctions: 'I don't mean ordinary sleep; I mean hypnosis. As you see, you are hypnotized, you can't open your eyes', etc., 'and in any case, there's no need for you to go to sleep', and so on. I feel sure that many other physicians who practise psychotherapy can get out of such difficulties with more skill than I can. If so, they may adopt some procedure other than mine. It [109] seems to me, however, that if one can reckon with such frequency on finding oneself in an embarrassing situation through the use of a particular word, one will be wise to avoid both the word and the embarrassment. When, therefore, my first attempt did not lead either to somnambulism or to a degree of hypnosis involving marked physical changes, I ostensibly dropped hypnosis, and only asked for 'concentration'; and I ordered the patient to lie down and deliberately shut his eyes as a means of achieving this 'concentration'. It is possible that in this way I obtained

with only a slight effort the deepest degree of hypnosis that could be reached in the particular case.

But in doing without somnambulism I might be depriving myself of a precondition without which the cathartic method seemed unusable. For that method clearly rested on the patients in their changed state of consciousness having access to memories and being able to recognize connections which appeared not to be present in their normal state of consciousness. If the somnambulistic extension of memory were absent there could also be no possibility of establishing any determining causes which the patient could present to the physician as something unknown to him (the patient); and, of course, it is precisely the pathogenic memories which, as we have already said in our 'Preliminary Communication' [p. 8 above], are 'absent from the patients' memory when they are in a normal psychical state, or are only present in a highly summary form'.

I was saved from this new embarrassment by remembering that I had myself seen Bernheim producing evidence that the memories of events during somnambulism are only *apparently* forgotten in the waking state and can be revived by a mild word of command and a pressure with the hand intended to indicate a different state of consciousness. He had, for instance, given a woman in a state of somnambulism a negative hallucination to the effect that he was no longer present, and had then endeavoured to draw her attention to himself in a great variety of ways, including some of a decidedly aggressive kind. He did not succeed. After she had been woken up he asked her to tell him what he had done to her while she thought he was not there. She replied in surprise that she knew nothing of it. But he did not accept this. He insisted that she could remember everything and laid his hand on her forehead to help her to [110] recall it. And lo and behold! she ended by describing everything that she had ostensibly not perceived during her somnambulism and ostensibly not remembered in her waking state.

This astonishing and instructive experiment served as my model. I decided to start from the assumption that my patients knew everything that was of any pathogenic significance and that it was only a question of obliging them to communicate it. Thus when I reached a point at which, after asking a patient some question such as: 'How long have you had this symptom?' or: 'What was its origin?', I was met with the answer: 'I really don't know', I proceeded as follows. I placed my hand on the patient's forehead or took her head between my hands and said: 'You will think of it [*einfallen*]^{T} under the pressure of my hand. At the moment *Einfall* at which I relax my pressure you will see something in front of you or

something will come into your head [*Einfall*]. Catch hold of it. It will be what we are looking for. – Well, what have you seen or what has occurred to you [*eingefallen*]?'

[111] On the first occasions on which I made use of this procedure (it was not with Miss Lucy R.[1]) I myself was surprised to find that it yielded me the precise results that I needed. And I can safely say that it has scarcely ever left me in the lurch since then. It has always pointed the way which the analysis should take and has enabled me to carry through every such analysis to an end without the use of somnambulism. Eventually I grew so confident that, if patients answered, 'I see nothing' or 'nothing has occurred to me [*eingefallen*]', I could dismiss this as an impossibility and could assure them that they had certainly become aware of what was wanted but had refused to believe that that was so and had rejected it. I told them I was ready to repeat the procedure as often as they liked and they would see the same thing every time. I turned out to be invariably right. The patients had not yet learnt to relax their critical faculty. They had rejected the memory that had come up or the idea [*Einfall*] that had occurred to them, on the ground that it was unserviceable and an irrelevant interruption; and after they had told it to me it always proved to be what was wanted. Occasionally, when, after three or four pressures, I had at last extracted the information, the patient would reply: 'As a matter of fact I knew that the first time, but it was just what I didn't want to say', or 'I hoped that would not be it.'

This business of enlarging what was supposed to be a restricted consciousness was laborious – far more so, at least, than an investigation

1 [Freud's first use of the 'pressure technique' seems to have been with Fräulein Elisabeth von R. (see below, p. 129), though his statement there is not completely unambiguous. Further accounts of this procedure, in addition to those in the text above and in the passage just referred to, can be found on pp. 136 f. and 241 ff. below. There is a slight apparent inconsistency in these accounts. In the present one, the patient is told that she will see something or have some idea 'at the moment at which I relax my pressure'; on p. 129 below, she is told that this will occur 'at the moment of the pressure'; and on p. 241 that it will occur 'all the time the pressure lasts'. It is not known exactly when Freud abandoned this pressure technique. He had certainly done so before 1904, since in his contribution of that date to Löwenfeld's book on obsessions he explicitly remarks that he avoids touching his patients in any way (1904*a*), *RSE*, **7**, 224. But it seems likely that he had already given up the practice before 1900, for he makes no mention of it in the short account of his procedure given near the beginning of Chapter II of *The Interpretation of Dreams* (1900*a*), ibid., **4**, 90. Incidentally, in this latter passage Freud still recommends that the patient should keep his eyes shut during analysis. This last remnant (apart from lying down) of the original hypnotic procedure was also explicitly disrecommended in the sentence already quoted from his contribution to Löwenfeld (1904*a*). – We have fairly exact information upon the period of Freud's use of hypnotism proper. In a letter to Fliess of December 28, 1887 (Freud, 1950*a*, Letter 2) he wrote: 'During the last few weeks I have taken up hypnosis.' And in a lecture given before the Wiener medizinisches Doktorencollegium on December 12, 1904 (Freud, 1905*a*), *RSE*, **7**, 270, he declared: 'I have not used hypnosis for therapeutic purposes for some eight years (except for a few special experiments).' His use of hypnotism therefore fell approximately between the years 1887 and 1896. In connection with the 'pressure technique', see also the second paper on 'The Neuropsychoses of Defence' (1896*b*), ibid., **3**, 186.]

during somnambulism. But it nevertheless made me independent of somnambulism, and gave me insight into the motives which often determine the 'forgetting' of memories. I can affirm that this forgetting is often intentional and desired; and its success is never more than *apparent*.

I found it even more surprising perhaps that it was possible by the same procedure to bring back numbers and dates which, on the face of it, had long since been forgotten, and so to reveal how unexpectedly accurate memory can be.

The fact that in looking for numbers and dates our choice is so limited enables us to call to our help a proposition familiar to us from the theory [112] of aphasia, namely that recognizing something is a lighter task for memory than thinking of it spontaneously.[1] Thus, if a patient is unable to remember the year or month or day when a particular event occurred, we can repeat to him the dates of the possibly relevant years, the names of the twelve months and the thirty-one numbers of the days of the month, assuring him that when we come to the right number or the right name his eyes will open of their own accord or that he will feel which is the right one. In the great majority of cases the patient will in fact decide on a particular date. Quite often (as in the case of Frau Cäcilie M.) it is possible to prove from documents belonging to the period in question that the date has been recognized correctly; while in other cases and on other occasions the indisputable accuracy of the date thus chosen can be inferred from the context of the facts remembered. For instance, after a patient had had her attention drawn to the date which had been arrived at by this 'counting over' method, she said: 'Why, that's my father's birthday!' and added: 'Of course! It was because it was his birthday that I was expecting the event we were talking about.'

Here I can only touch upon the theme in passing. The conclusion I drew from all these observations was that experiences which have played an important pathogenic part, and all their subsidiary concomitants, are accurately retained in the patient's memory even when they seem to be forgotten – when he is unable to call them to mind.[2]

1 [Freud had written his book on aphasia (1891*b*) not long before.]

2 As an example of the technique which I have described above of carrying out investigations in non-somnambulistic states – that is, where there is no extension of consciousness – I will describe an instance which I happen to have analysed in the course of the last few days. I was treating a woman of thirty-eight, suffering from anxiety neurosis (agoraphobia, attacks of fear of death, etc.). Like so many such patients, she had a disinclination to admitting that she had acquired these troubles in her married life and would have liked to push them back into her early youth. Thus she told me that she was seventeen when she had had a first attack of dizziness, with anxiety and feelings of faintness, in the street in her small native town, and that these attacks had recurred from time to time, till a few years ago they had given place to her present disorder. I suspected that these first attacks of dizziness, in which the anxiety faded more and more into the background, were hysterical and I made up my mind to embark on an analysis of them. To begin with she only

[113] After this long but unavoidable digression I will return to the case of Miss Lucy R. As I have said, then, my attempts at hypnosis with her did not produce somnambulism. She simply lay quietly in a state open to some mild degree of influence, with her eyes closed all the time, her fea-
[114] tures somewhat rigid, and without moving hand or foot. I asked her if

knew that this first attack came over her while she was out shopping in the principal street. 'What were you going to buy?' – 'Different things, I believe; they were for a ball I had been invited to.' – 'When was this ball to take place?' – 'Two days later, I think.' – 'Something must have happened to agitate you a few days before, something that made an impression on you.' – 'I can't think of anything. After all, it was twenty-one years ago.' – 'That makes no difference; you will remember all the same. I shall press on your head, and when I relax the pressure, you will think of something or see something, and you must tell me what that is.' I went through this procedure; but she remained silent. 'Well, has nothing occurred to you?' – 'I have thought of something, but it can't have any connection with this.' – 'Tell it to me anyway.' – 'I thought of a friend of mine, a girl, who is dead. But she died when I was eighteen – a year later, that is.' – 'We shall see. Let's stick to this point. What about this friend of yours?' – 'Her death was a great shock to me, as I used to see a lot of her. A few weeks earlier another girl had died, and that had made a great stir in the town. So after all, I must have been seventeen at the time.' – 'There, you see, I told you we could rely on the things that come into your head under the pressure of my hand. Now, can you remember what you were thinking about when you felt dizzy in the street?' – 'I wasn't thinking of anything; I only felt dizzy.' – 'That's not possible. States like that never happen without being accompanied by some idea. I shall press once more and the thought you had will come back to you. . . . Well, what has occurred to you?' – 'The idea that I am the third.' – 'What does that mean?' – 'When I got the attack of dizziness I must have thought: "Now I am dying, like the other two girls."' – 'That was the idea, then. As you were having the attack you thought of your friend. So her death must have made a great impression on you.' – 'Yes, it did. I can remember now that when I heard of her death I felt it was dreadful to be going to a ball, while she was dead. But I was looking forward so much to the ball and was so busy with preparations for it; I didn't want to think of what had happened at all.' (We may observe here a deliberate repression from consciousness, which rendered the patient's memory of her friend pathogenic.)

The attack was now to some extent explained. But I still needed to know of some precipitating factor which had provoked the memory at that particular time. I then formed what happened to be a lucky conjecture. 'Do you remember the exact street you were walking along just then?' – 'Certainly. It was the principal street, with its old houses. I can see them now.' – 'And where was it that your friend lived?' – 'In a house in the same street. I had just passed it, and I had the attack a couple of houses further on.' – 'So when you went by the house it reminded you of your dead friend, and you were once more overcome by the contrast which you did not want to think of.'

I was still not satisfied. There might, I thought, be something else at work as well that had aroused or reinforced the hysterical disposition of a girl who had till then been normal. My suspicions turned to her monthly periods as an appropriate factor, and I asked: 'Do you know at what time in the month your period came on?' The question was not a welcome one. 'Do you expect me to know that, too? I can only tell you that I had them very seldom then and very irregularly. When I was seventeen I only had one once.' – 'Very well, then, we will find out when this once was by counting over.' I did the counting over, and she decided definitely on one particular month and hesitated between two days immediately preceding the date of a fixed holiday. 'Does that fit in somehow with the date of the ball?' She answered sheepishly: 'The ball was on the holiday. And now I remember, too, what an impression it made on me that my only period that year should have had to come on just before the ball. It was my first ball.'

There is no difficulty now in reconstructing the interconnection between the events, and we can now see into the mechanism of this hysterical attack. It is true that the achievement of this result had been a laborious business. It required complete confidence in my technique on my side, and the occurrence to the patient of a few key ideas, before it was possible to reawaken, after an interval of twenty-one years, these details of a forgotten experience in a sceptical person who was, in fact, in a waking state. But once all this had been gone through, the whole thing fitted together.

she could remember the occasion on which she first had the smell of burnt pudding. 'Oh yes, I know exactly. It was about two months ago, two days before my birthday. I was with the children in the schoolroom and was playing at cooking with them' (they were two little girls). 'A letter was brought in that had just been left by the postman. I saw from the postmark and the handwriting that it was from my mother in Glasgow and wanted to open it and read it; but the children rushed at me, tore the letter out of my hands and cried: "No, you shan't read it now! It must be for your birthday; we'll keep it for you!" While the children were having this game with me there was suddenly a strong smell. They had forgotten the pudding they were cooking and it was getting burnt. Ever since this I have been pursued by the smell. It is there all the time and becomes stronger when I am agitated.'

'Do you see this scene clearly before your eyes?' – 'As large as life, just as I experienced it.' – 'What could there be about it that was so agitating?' – 'I was moved because the children were so affectionate to [115] me.' – 'Weren't they always?' – 'Yes – but just when I got the letter from my mother.' – 'I don't understand why there is a contrast between the children's affection and your mother's letter, for that's what you seem to be suggesting.' – 'I was intending to go back to my mother's, and the thought of leaving the dear children made me feel so sad.' – 'What's wrong with your mother? Has she been feeling lonely and sent for you? Or was she ill at the time, and were you expecting news of her?' – 'No; she isn't very strong, but she's not exactly ill, and she has a companion with her.' – 'Then why must you leave the children?' – 'I couldn't bear it any longer in the house. The housekeeper, the cook and the French governess seem to have thought that I was putting myself above my station. They joined in a little intrigue against me and said all sorts of things against me to the children's grandfather, and I didn't get as much support as I had expected from the two gentlemen when I complained to them. So I gave notice to the Director' (the children's father). 'He answered in a very friendly way that I had better think the matter over for a couple of weeks before I finally gave him my decision. I was in this state of uncertainty at the time, and thought I should be leaving the house; but I have stayed on.' – 'Was there something particular, apart from their fondness for you, which attached you to the children?' – 'Yes. Their mother was a distant relation of my mother's, and I had promised her on her deathbed that I would devote myself with all my power to the children, that I would not leave them and that I would take their mother's place with them. In giving notice I had broken this promise.'

This seemed to complete the analysis of the patient's subjective sensation of smell. It had turned out in fact to have been an objective sensation originally, and one which was intimately associated with an experience – a little scene – in which opposing affects had been in conflict with each other: her regret at leaving the children and the slights which were nevertheless urging her to make up her mind to do so. Her mother's letter had not unnaturally reminded her of her reasons for this decision, since it was her intention to join her mother on leaving here. The conflict between her affects had elevated the moment of the letter's arrival into a trauma, and the sensation of smell that was associated with this trauma
[116] persisted as its symbol. It was still necessary to explain why, out of all the sense perceptions afforded by the scene, she had chosen this smell as a symbol. I was already prepared, however, to use the chronic affection of her nose as a help in explaining the point. In response to a direct question she told me that just at that time she had once more been suffering from such a heavy cold in the nose that she could hardly smell anything. Nevertheless, while she was in her state of agitation [*Erregung*][T] she perceived the smell of the burnt pudding, which broke through the organically determined loss of her sense of smell.

But I was not satisfied with the explanation thus arrived at. It all sounded highly plausible, but there was something that I missed, some adequate reason why these agitations and this conflict of affects should have led to hysteria rather than anything else. Why had not the whole thing remained on the level of normal psychical life? In other words, what was the justification for the conversion which occurred? Why did she not always call to mind the scene itself, instead of the associated sensation which she singled out as a symbol of the recollection? Such questions might be over-curious and superfluous if we were dealing with a hysteric of long standing in whom the mechanism of conversion was habitual. But it was not until this trauma, or at any rate this small tale of trouble, that the girl had acquired hysteria.

Now I already knew from the analysis of similar cases that before hysteria can be acquired for the first time one essential condition must be fulfilled: an idea [*Vorstellung*] must be *intentionally repressed from consciousness*[1] and excluded from associative [*assoziativen*] modification. In my view this intentional repression is also the basis for the conversion, whether total or partial, of the sum of excitation [*Erregungssumme*]. The sum of excitation, being cut off from psychical association, finds its way all the more easily along the wrong path to a

1 [See footnote, p. 9 above.]

somatic innervation. The basis for repression itself can only be a feeling of unpleasure, the incompatibility between the single idea that is to be repressed and the dominant mass of ideas constituting the ego. The repressed idea takes its revenge, however, by becoming pathogenic.

I accordingly inferred from Miss Lucy R.'s having succumbed to hysterical conversion at the moment in question that among the determinants of the trauma there must have been one which she had [117] sought intentionally to leave in obscurity and had made efforts to forget. If her fondness for the children and her sensitiveness on the subject of the other members of the household were taken together, only one conclusion could be reached. I was bold enough to inform my patient of this interpretation [*Deutung*][T]. I said to her: 'I cannot think that these are all the reasons for your feelings about the children. I believe that really you are in love with your employer, the Director, though perhaps without being aware of it yourself, and that you have a secret hope of taking their mother's place in actual fact. And then we must remember the sensitiveness you now feel towards the servants, after having lived with them peacefully for years. You're afraid of their having some inkling of your hopes and making fun of you.'

She answered in her usual laconic fashion: 'Yes, I think that's true.' – 'But if you knew you loved your employer why didn't you tell me?' – 'I didn't know – or rather I didn't want to know. I wanted to drive it out of my head and not think of it again; and I believe latterly I have succeeded.'[1] – 'Why was it that you were unwilling to admit this inclination? Were you ashamed of loving a man?' – 'Oh no, I'm not unreasonably prudish. We're not responsible for our feelings, anyhow. It was distressing to me only because he is my employer and I am in his service and live in his house. I don't feel the same complete independence towards him that I could towards anyone else. And then I am only a poor girl and he is such a rich man of good family. People would laugh at me if they had any idea of it.'

1 I have never managed to give a better description than this of the strange state of mind in which one knows and does not know a thing at the same time. It is clearly impossible to understand it unless one has been in such a state oneself. I myself have had a very remarkable experience of this sort, which is still clearly before me. If I try to recollect what went on in my mind at the time I can get hold of very little. What happened was that I saw something which did not fit in at all with my expectation; yet I did not allow what I saw to disturb my fixed plan in the least, though the perception should have put a stop to it. I was unconscious of any contradiction in this; nor was I aware of my feelings of repulsion, which must nevertheless undoubtedly have been responsible for the perception producing no psychical effect. I was afflicted by that blindness of the seeing eye which is so astonishing in the attitude of mothers to their daughters, husbands to their wives and rulers to their favourites.

[118] She now showed no resistance to throwing light on the origin of this inclination. She told me that for the first few years she had lived happily in the house, carrying out her duties and free from any unfulfillable wishes. One day, however, her employer, a serious, overworked man whose behaviour towards her had always been reserved, began a discussion with her on the lines along which children should be brought up. He unbent more and was more cordial than usual and told her how much he depended on her for looking after his orphaned children; and as he said this he looked at her meaningfully. . . . Her love for him had begun at that moment, and she even allowed herself to dwell on the gratifying hopes which she had based on this talk. But when there was no further development, and when she had waited in vain for a second hour's intimate exchange of views, she decided to banish the whole business from her mind. She entirely agreed with me that the look she had caught during their conversation had probably sprung from his thoughts about his wife, and she recognized quite clearly that there was no prospect of her feelings for him meeting with any return.

I expected that this discussion would bring about a fundamental change in her condition. But for the time being this did not occur. She continued to be in low spirits and depressed. She felt somewhat refreshed in the mornings by a course of hydropathic treatment which I prescribed for her at the same time. The smell of burnt pudding did not disappear completely, though it became less frequent and weaker. It only came on, she said, when she was very much agitated. The persistence of this mnemic symbol led me to suspect that, in addition to the main scene, it had taken over the representation of the many minor traumas subsidiary to that scene. We therefore looked about for anything else that might have to do with the scene of the burnt pudding; we went into the subject of the domestic friction, the grandfather's behaviour, and so on, and as we did so the burnt smell faded more and more. During this time, too, the treatment was interrupted for a considerable while, owing to a fresh attack of her nasal disorder, and this now led to the discovery of the caries of the ethmoid [p. 94 above].

On her return she reported that at Christmas she had received a great many presents from the two gentlemen of the house and even from the
[119] servants, as though they were all anxious to make it up with her and to wipe out her memory of the conflicts of the last few months. But these signs of goodwill had not made any impression on her.

When I enquired once more about the smell of burnt pudding, she informed me that it had quite disappeared but that she was being

bothered by another, similar smell, resembling cigar smoke. It had been there earlier as well, she thought, but had, as it were, been covered by the smell of the pudding. Now it had emerged by itself.

I was not very well satisfied with the results of the treatment. What had happened was precisely what is always brought up against purely symptomatic treatment: I had removed one symptom only for its place to be taken by another. Nevertheless, I did not hesitate to set about the task of getting rid of this new mnemic symbol by analysis.

But this time she did not know where the subjective olfactory sensation came from – on what important occasion it had been an objective one. 'People smoke every day in our house,' she said, 'and I really don't know whether the smell I notice refers to some special occasion.' I then insisted that she should try to remember under the pressure of my hand. I have already mentioned [p. 101 above] that her memories had the quality of plastic vividness, that she was a 'visual' type. And in fact, at my insistence, a picture gradually emerged before her, hesitatingly and piecemeal to begin with. It was the dining room in her house, where she was waiting with the children for the two gentlemen to return to luncheon from the factory. 'Now we are all sitting round the table, the gentlemen, the French governess, the housekeeper, the children and myself. But that's like what happens every day.' – 'Go on looking at the picture; it will develop and become more specialized.' – 'Yes, there is a guest. It's the chief accountant. He's an old man and he is as fond of the children as if they were his own grandchildren. But he comes to lunch so often that there's nothing special in that either.' – 'Be patient and just keep looking at the picture; something's sure to happen.' – 'Nothing's happening. We're getting up from the table; the children say their goodbyes, and they go upstairs with us as usual to the second floor.' – 'And then?' – 'It *is* a special occasion, after all. I recognize the scene now. As the children say goodbye, the accountant tries to kiss them. My employer flares up and actually shouts at him: "Don't kiss the children!" I feel a stab at my heart; [120] and as the gentlemen are already smoking, the cigar smoke sticks in my memory.'

This, then, was a second and deeper-lying scene which, like the first, operated as a trauma and left a mnemic symbol behind it. But to what did this scene owe its effectiveness? 'Which of the two scenes was the earlier,' I asked, 'this one or the one with the burnt pudding?' – 'The scene I have just told you about was the earlier, by almost two months.' – 'Then why did you feel this stab when the children's father stopped the old man? His reprimand wasn't aimed at you.' – 'It wasn't

right of him to shout at an old man who was a valued friend of his and, what's more, a guest. He could have said it quietly.' – 'So it was only the violent way he put it that hurt you? Did you feel embarrassed on his account? Or perhaps you thought: "If he can be so violent about such a small thing with an old friend and guest, how much more so might he be with me if I were his wife".' – 'No, that's not it.' – 'But it had to do with his violence, hadn't it?' – 'Yes, about the children being kissed. He has never liked that.'

And now, under the pressure of my hand, the memory of a third and still earlier scene emerged, which was the really operative trauma and which had given the scene with the chief accountant its traumatic effectiveness. It had happened a few months earlier still that a lady who was an acquaintance of her employer's came to visit them, and on her departure kissed the two children on the mouth. Their father, who was present, managed to restrain himself from saying anything to the lady, but after she had gone, his fury burst upon the head of the unlucky governess. He said he held her responsible if anyone kissed the children on the mouth, that it was her duty not to permit it and that she was guilty of a dereliction of duty if she allowed it; if it ever happened again he would entrust his children's upbringing to other hands. This had happened at a time when she still thought he loved her, and was expecting a repetition of their first friendly talk. The scene had crushed her hopes. She had said to herself: 'If he can fly out at me like this and make such threats over such a trivial matter, and one for which, moreover, I am not in the least responsible, I must have made a mistake. He can never have had any warm feelings for me, or they would have taught him to treat me with
[121] more consideration.' – It was obviously the recollection of this distressing scene which had come to her when the chief accountant had tried to kiss the children and had been reprimanded by their father.

After this last analysis, when, two days later, Miss Lucy visited me once more, I could not help asking her what had happened to make her so happy. She was as though transfigured. She was smiling and carried her head high. I thought for a moment that after all I had been wrong about the situation, and that the children's governess had become the Director's fiancée. But she dispelled my notion. 'Nothing has happened. It's just that you don't know me. You have only seen me ill and depressed. I'm always cheerful as a rule. When I woke yesterday morning the weight was no longer on my mind, and since then I have felt well.' – 'And what do you think of your prospects in the house?' – 'I am quite clear on the subject. I know I have none, and I shan't make myself unhappy over

it.' – 'And will you get on all right with the servants now?' – 'I think my own oversensitiveness was responsible for most of that.' – 'And are you still in love with your employer?' – 'Yes, I certainly am, but that makes no difference. After all, I can have thoughts and feelings to myself.'

I then examined her nose and found that its sensitivity to pain and reflex excitability had been almost completely restored. She was also able to distinguish between smells, though with uncertainty and only if they were strong. I must leave it an open question, however, how far her nasal disorder may have played a part in the impairment of her sense of smell.

This treatment lasted in all for nine weeks. Four months later I met the patient by chance in one of our summer resorts. She was in good spirits and assured me that her recovery had been maintained.

DISCUSSION

I am not inclined to underestimate the importance of the case that I have here described, even though the patient was suffering only from a slight and mild hysteria and though only a few symptoms were involved. On the contrary it seems to me an instructive fact that even an illness such as this, so unproductive when regarded as a neurosis, called for so many psychical determinants. Indeed, when I consider this case history more [122] closely, I am tempted to regard it as a model instance of one particular type of hysteria, namely the form of this illness which can be acquired even by a person of sound heredity, as a result of appropriate experiences. It should be understood that I do not mean by this a hysteria which is independent of *any* pre-existing disposition. It is probable that no such hysteria exists. But we do not recognize a disposition of this sort in a subject until he has actually become a hysteric; for previously there was no evidence of its existence. A neuropathic disposition, as generally understood, is something different. It is already marked out before the onset of the illness by the amount of the subject's hereditary taint or the sum of his individual psychical abnormalities. So far as my information goes, there was no trace in Miss Lucy R. of either of these factors. Her hysteria can therefore be described as an acquired one, and it presupposed nothing more than the possession of what is probably a very widespread proclivity – the proclivity to acquire hysteria. We have as yet scarcely a notion of what the features of this proclivity may be. In cases of this kind, however, the main emphasis falls upon the nature of the trauma, though taken in conjunction, of course, with the subject's reaction to it. It turns out to be a *sine qua non* for the acquisition of hysteria

that an incompatibility [*Unverträglichkeit*] should develop between the ego and some idea presented to it. I hope to be able to show elsewhere[1] how different neurotic disturbances arise from the different methods adopted by the 'ego' in order to escape from this incompatibility. The hysterical method of defence – for which, as we have seen, the possession of a particular proclivity is necessary – lies in the conversion of the excitation into a somatic innervation; and the advantage of this is that the incompatible idea [*unverträgliche Vorstellung*] is forced out of the ego's consciousness. In exchange, that consciousness now contains the physical reminiscence which has arisen through conversion (in our case, the patient's subjective sensations of smell) and suffers from the affect
[123] which is more or less clearly attached to precisely that reminiscence. The situation which has thus been brought about is now not susceptible to further change; for the incompatibility which would have called for a removal of the affect no longer exists, thanks to the repression and conversion. Thus the mechanism which produces hysteria represents on the one hand an act of moral cowardice and on the other a defensive measure which is at the disposal of the ego. Often enough we have to admit that fending off increasing excitations by the generation of hysteria is, in the circumstances, the most expedient thing to do; more frequently, of course, we shall conclude that a greater amount of moral courage would have been of advantage to the person concerned.

The actual traumatic moment, then, is the one at which the incompatibility forces itself upon the ego and at which the latter decides on the repudiation of the incompatible idea. That idea is not annihilated by a repudiation of this kind, but merely repressed into the unconscious.[2] When this process occurs for the first time there comes into being a nucleus and centre of crystallization for the formation of a psychical group divorced from the ego – a group around which everything which would imply an acceptance of the incompatible idea subsequently collects. The splitting of consciousness [*Spaltung des Bewusstseins*] in these cases of acquired hysteria is accordingly a deliberate and intentional one. At least it is often *introduced* by an act of volition; for the actual outcome is something different from what the subject intended. What he wanted was to do away with an idea, as though it had never appeared, but all he succeeds in doing is to isolate it psychically.

1 [Freud sketched out the distinction between the mechanisms used in hysteria, obsessions and paranoia in a communication to Fliess of January 1, 1896 (Freud, 1950*a*, Draft K); in the following May he published these findings in his second paper on 'The Neuropsychoses of Defence' (1896*b*), *RSE*, **3**, 173 ff.]

2 [See footnote 2, p. 41 above.]

In the history of our present patient the traumatic moment was the moment of her employer's outburst against her about his children being kissed by the lady. For a time, however, that scene had no manifest effect. (It may be that her oversensitiveness and low spirits began from it, but I cannot say.) Her hysterical symptoms did not start until later, at moments which may be described as 'auxiliary'.[1] The characteristic feature of such an auxiliary moment is, I believe, that the two divided psychical groups temporarily converge in it, as they do in the extended consciousness which occurs in somnambulism. In Miss Lucy R.'s case [124]
the first of the auxiliary moments, at which conversion took place, was the scene at table when the chief accountant tried to kiss the children. Here the traumatic memory was playing a part: she did not behave as though she had got rid of everything connected with her devotion to her employer. (In the history of other cases these different moments coincide; conversion occurs as an immediate effect of the trauma.)

The second auxiliary moment repeated the mechanism of the first one fairly exactly. A powerful impression temporarily reunited the patient's consciousness, and conversion once more took the path which had been opened out on the first occasion. It is interesting to notice that the second symptom to develop masked the first, so that the first was not clearly perceived until the second had been cleared out of the way. It also seems to me worthwhile remarking upon the reversed course which had to be followed by the analysis as well. I have had the same experience in a whole number of cases; the symptoms that had arisen later masked the earlier ones, and the key to the whole situation lay only in the last symptom to be reached by the analysis.

The therapeutic process in this case consisted in compelling the psychical group that had been split off to unite once more with the ego consciousness. Strangely enough, success did not run *pari passu* with the amount of work done. It was only when the last piece of work had been completed that recovery suddenly took place.

1 [Freud had already discussed such 'auxiliary' traumatic moments in Section I of his first paper on 'The Neuropsychoses of Defence' (1894*a*), *RSE*, **3**, 47.]

CASE 4
KATHARINA —— (*FREUD*)

[125] In the summer vacation of the year 189–[1] I made an excursion into the Hohe Tauern[2] so that for a while I might forget medicine and more particularly the neuroses. I had almost succeeded in this when one day I turned aside from the main road to climb a mountain which lay somewhat apart and which was renowned for its views and for its well-run refuge hut. I reached the top after a strenuous climb and, feeling refreshed and rested, was sitting deep in contemplation of the charm of the distant prospect. I was so lost in thought that at first I did not connect it with myself when these words reached my ears: 'Are you a doctor, sir?' But the question was addressed to me, and by the rather sulky-looking girl of perhaps eighteen who had served my meal and had been spoken to by the landlady as 'Katharina'. To judge by her dress and bearing, she could not be a servant, but must no doubt be a daughter or relative of the landlady's.

Coming to myself I replied: 'Yes, I'm a doctor: but how did you know that?'

'You wrote your name in the visitors' book, sir. And I thought if you had a few moments to spare . . . The truth is, sir, my nerves are bad. I went to see a doctor in L—— about them and he gave me something for them; but I'm not well yet.'

So there I was with the neuroses once again – for nothing else could very well be the matter with this strong, well-built girl with her unhappy look. I was interested to find that neuroses could flourish in this way at a height of over 6,000 feet; I questioned her further therefore. I report the conversation that followed between us just as it is impressed on my memory and I have not altered the patient's dialect.[3]

'Well, what is it you suffer from?'

'I get so out of breath. Not always. But sometimes it catches me so that I think I shall suffocate.'

[126] This did not, at first sight, sound like a nervous symptom. But soon it occurred to me that probably it was only a description that stood for an anxiety attack: she was choosing shortness of breath out of the complex

1 [The facts of this case have been thoroughly researched by Fichtner & Hirschmüller (1985) and Swales (1988). The date of the summer vacation was 1893. The 'refuge hut' described below was the newly opened Ottohaus hotel on the Rax mountain. 'Katharina' was then eighteen years old.]

2 [One of the highest ranges in the Eastern Alps.]

3 [No attempt has been made in the English translation to imitate this dialect.]

of sensations arising from anxiety and laying undue stress on that single factor.

'Sit down here. What is it like when you get "out of breath"?'

'It comes over me all at once. First of all it's like something pressing on my eyes. My head gets so heavy, there's a dreadful buzzing, and I feel so giddy that I almost fall over. Then there's something crushing my chest so that I can't get my breath.'

'And you don't notice anything in your throat?'

'My throat's squeezed together as though I were going to choke.'

'Does anything else happen in your head?'

'Yes, there's a hammering, enough to burst it.'

'And don't you feel at all frightened while this is going on?'

'I always think I'm going to die. I'm brave as a rule and go about everywhere by myself – into the cellar and all over the mountain. But on a day when that happens I don't dare go anywhere; I think all the time someone's standing behind me and going to catch hold of me all at once.'

So it was in fact an anxiety attack, and introduced by the signs of a hysterical 'aura'[1] – or, more correctly, it was a hysterical attack the content of which was anxiety. Might there not probably be some other content as well?

'When you have an attack do you think of something? and always the same thing? or do you see something in front of you?'

'Yes. I always see an awful face that looks at me in a dreadful way, so that I'm frightened.'

Perhaps this might offer a quick means of getting to the heart of the matter.

'Do you recognize the face? I mean, is it a face that you've really seen some time?'

'No.'

'Do you know what your attacks come from?'

'No.'

'When did you first have them?'

'Two years ago, while I was still living on the other mountain with my [127]
aunt. (She used to run a refuge hut there, and we moved here eighteen months ago.)[2] But they keep on happening.'

Was I to make an attempt at an analysis? I could not venture to transplant hypnosis to these altitudes, but perhaps I might succeed with a simple talk. I should have to try a lucky guess. I had found often enough

1 [The premonitory sensations preceding an epileptic or hysterical attack.]

2 [As Freud reveals below Katharina was in fact the landlady's *daughter*, not her niece. The 'refuge hut' on the other mountain was the Hotel zum Baumgartner, on the Schneeberg. Katharina's mother had moved across the valley with all her children as a result of the events described below.]

that in girls anxiety was a consequence of the horror by which a virginal mind is overcome when it is faced for the first time with the world of sexuality.[1]

So I said: 'If you don't know, I'll tell you how *I* think you got your attacks. At that time, two years ago, you must have seen or heard something that very much embarrassed you, and that you'd much rather not have seen.'

'Heavens, yes!' she replied, 'that was when I caught my uncle with the girl, with Franziska, my cousin.'

'What's this story about a girl? Won't you tell me all about it?'

'You can say *anything* to a doctor, I suppose. Well, at that time, you know, my uncle – the husband of the aunt you've seen here – kept the inn on the ——kogel.[2] Now they're separated [*geschieden*],[3] and it's my fault they were separated, because it was through me that it came out that he was carrying on with Franziska.'

'And how did you discover it?'

'This way. One day two years ago some gentlemen had climbed the mountain and asked for something to eat. My aunt wasn't at home, and Franziska, who always did the cooking, was nowhere to be found. And my uncle was not to be found either. We looked everywhere, and at last Alois, the little boy, my cousin, said: "Why, Franziska must be in Father's
[128] room!" And we both laughed; but we weren't thinking anything bad. Then we went to my uncle's room but found it locked. That seemed strange to me. Then Alois said: "There's a window in the passage where you can look into the room." We went into the passage; but Alois wouldn't go to the window and said he was afraid. So I said: "You silly boy! I'll go. I'm not a bit afraid." And I had nothing bad in my mind. I looked in. The room was rather dark, but I saw my uncle and Franziska; he was lying on her.'

1 I will quote here the case in which I first recognized this causal connection. I was treating a young married woman who was suffering from a complicated neurosis and, once again [cf. p. 99 *n*. 2 above], was unwilling to admit that her illness arose from her married life. She objected that while she was still a girl she had had attacks of anxiety, ending in fainting fits. I remained firm. When we had come to know each other better she suddenly said to me one day: 'I'll tell you now how I came by my attacks of anxiety when I was a girl. At that time I used to sleep in a room next to my parents'; the door was left open and a nightlight used to burn on the table. So more than once I saw my father get into bed with my mother and heard sounds that greatly excited me. It was then that my attacks came on.' – [Two cases of this kind are mentioned by Freud in a letter to Fliess of May 30, 1893 (Freud, 1950*a*, Letter 12). Cf. also Section II of the first paper on anxiety neurosis (1895*b*), *RSE*, **3**.]

2 [Disguised name for the Schneeberg. The cousin mentioned above was her mother's niece; and the 'uncle' was of course her father.]

3 [Translated as 'divorced' in *SE*, which is linguistically permissible but (in this case) factually incorrect.]

'Well?'

'I came away from the window at once, and leant up against the wall and couldn't get my breath – just what happens to me since. Everything went blank, my eyelids were forced together and there was a hammering and buzzing in my head.'

'Did you tell your aunt that very same day?'

'Oh no, I said nothing.'

'Then why were you so frightened when you found them together? Did you understand it? Did you know what was going on?'

'Oh no. I didn't understand anything at that time. I was only sixteen. I don't know what I was frightened about.'

'Fräulein Katharina, if you could remember now what was happening in you at that time, when you had your first attack, what you thought about it – it would help you.'

'Yes, if I could. But I was so frightened that I've forgotten everything.'

(Translated into the terminology of our 'Preliminary Communication' [p. 11 above], this means: 'The affect itself created a hypnoid state, whose products were then cut off from associative connection with the ego consciousness.')

'Tell me, Fräulein. Can it be that the head that you always see when you lose your breath is Franziska's head, as you saw it then?'

'Oh no, she didn't look so awful. Besides, it's a man's head.'

'Or perhaps your uncle's?'

'I didn't see his face as clearly as that. It was too dark in the room. And why should he have been making such a dreadful face just then?'

'You're quite right.'

(The road suddenly seemed blocked. Perhaps something might turn up in the rest of her story.)

'And what happened then?' [129]

'Well, those two must have heard a noise, because they came out soon afterwards. I felt very bad the whole time. I always kept thinking about it. Then two days later it was a Sunday and there was a great deal to do and I worked all day long. And on the Monday morning I felt giddy again and was sick, and I stopped in bed and was sick without stopping for three days.'

We [Breuer and I] had often compared the symptomatology of hysteria with a pictographic script which has become intelligible after the discovery of a few bilingual inscriptions. In that alphabet being sick means disgust. So I said: 'If you were sick three days later, I believe that means that when you looked into the room you felt disgusted.'

'Yes, I'm sure I felt disgusted,' she said reflectively, 'but disgusted at what?'

'Perhaps you saw something naked? What sort of state were they in?'

'It was too dark to see anything; besides they both of them had their clothes on. Oh, if only I knew what it was I felt disgusted at!'

I had no idea either. But I told her to go on and tell me whatever occurred to her, in the confident expectation that she would think of precisely what I needed to explain the case.

Well, she went on to describe how at last she reported her discovery to her aunt, who found that she was changed and suspected her of concealing some secret. There followed some very disagreeable scenes between her uncle and aunt, in the course of which the children came to hear a number of things which opened their eyes in many ways and which it would have been better for them not to have heard. At last her aunt decided to move with her children and niece and take over the present inn, leaving her uncle alone with Franziska, who had meanwhile become pregnant. After this, however, to my astonishment she dropped these threads and began to tell me two sets of older stories, which went back two or three years earlier than the traumatic moment. The first set related to occasions on which the same uncle had made sexual advances to her herself, when she was only fourteen years old. She described how she had once gone with him on an expedition down into the valley in the winter and had spent the night in the inn there. He sat in the bar drinking and
[130] playing cards, but she felt sleepy and went up to bed early in the room they were to share on the upper floor. She was not quite asleep when he came up; then she fell asleep again and woke up suddenly 'feeling his body' in the bed. She jumped up and remonstrated with him: 'What are you up to, Uncle? Why don't you stay in your own bed?' He tried to pacify her: 'Go on, you silly girl, keep still. You don't know how nice it is.' – 'I don't like your "nice" things; you don't even let one sleep in peace.' She remained standing by the door, ready to take refuge outside in the passage, till at last he gave up and went to sleep himself. Then she went back to her own bed and slept till morning. From the way in which she reported having defended herself it seems to follow that she did not clearly recognize the attack as a sexual one. When I asked her if she knew what he was trying to do to her, she replied: 'Not at the time.' It had become clear to her much later on, she said; she had resisted because it was unpleasant to be disturbed in one's sleep and 'because it wasn't nice'.

I have been obliged to relate this in detail, because of its great importance for understanding everything that followed. – She went on to tell

me of yet other experiences of somewhat later date: how she had once again had to defend herself against him in an inn when he was completely drunk, and similar stories. In answer to a question as to whether on these occasions she had felt anything resembling her later loss of breath, she answered with decision that she had every time felt the pressure on her eyes and chest, but with nothing like the strength that had characterized the scene of discovery.

Immediately she had finished this set of memories she began to tell me a second set, which dealt with occasions on which she had noticed something between her uncle and Franziska. Once the whole family had spent the night in their clothes in a hay loft and she was woken up suddenly by a noise; she thought she noticed that her uncle, who had been lying between her and Franziska, was turning away, and that Franziska was just lying down. Another time they were stopping the night at an inn at the village of N——; she and her uncle were in one room and Franziska in an adjoining one. She woke up suddenly in the night and saw a tall white figure by the door, on the point of turning the handle: 'Goodness, is that you, Uncle? What are you doing at the door?' – 'Keep quiet. I was only looking for something.' – 'But the way out's by the *other* door.' – 'I'd just made a mistake' . . . and so on. [131]

I asked her if she had been suspicious at that time. 'No, I didn't think anything about it; I only just noticed it and thought no more about it.' When I enquired whether she had been frightened on these occasions too, she replied that she thought so, but she was not so sure of it this time.

At the end of these two sets of memories she came to a stop. She was like someone transformed. The sulky, unhappy face had grown lively, her eyes were bright, she was lightened and exalted. Meanwhile the understanding of her case had become clear to me. The later part of what she had told me, in an apparently aimless fashion, provided an admirable explanation of her behaviour at the scene of the discovery. At that time she had carried about with her two sets of experiences which she remembered but did not understand, and from which she drew no inferences. When she caught sight of the couple in intercourse, she at once established a connection between the new impression and these two sets of recollections, she began to understand them and at the same time to fend them off. There then followed a short period of working out, of 'incubation',[1] after which the symptoms of conversion set in, the vomiting as a substitute for moral and physical disgust. This solved the riddle. She had not been disgusted by the sight of the two people but by

1 [Cf. below, p. 118.]

the memory which that sight had stirred up in her. And, taking everything into account, this could only be the memory of the attempt on her at night when she had 'felt her uncle's body'.

So when she had finished her confession I said to her: 'I know now what it was you thought when you looked into the room. You thought: "Now he's doing with her what he wanted to do with me that night and those other times." That was what you were disgusted at, because you remembered the feeling when you woke up in the night and felt his body.'

'It may well be,' she replied, 'that that was what I was disgusted at and that that was what I thought.'

'Tell me just one thing more. You're a grown-up girl now and know all sorts of things . . .'

'Yes, now I am.'

'Tell me just one thing. What part of his body was it that you felt that night?'

[132] But she gave me no more definite answer. She smiled in an embarrassed way, as though she had been found out, like someone who is obliged to admit that a fundamental position has been reached where there is not much more to be said. I could imagine what the tactile sensation was which she had later learnt to interpret. Her facial expression seemed to me to be saying that she supposed that I was right in my conjecture. But I could not penetrate further, and in any case I owed her a debt of gratitude for having made it so much easier for me to talk to her than to the prudish ladies of my city practice, who regard whatever is natural as shameful.

Thus the case was cleared up. – But stop a moment! What about the recurrent hallucination of the head, which appeared during her attacks and struck terror into her? Where did it come from? I proceeded to ask her about it, and, as though *her* knowledge, too, had been extended by our conversation, she promptly replied: 'Yes, I know now. The head is my uncle's head – I recognize it now – but not from *that* time. Later, when all the disputes had broken out, my uncle gave way to a senseless rage against me. He kept saying that it was all my fault: if I hadn't chattered, it would never have come to a separation. He kept threatening he would do something to me; and if he caught sight of me at a distance his face would get distorted with rage and he would make for me with his hand raised. I always ran away from him, and always felt terrified that he would catch me some time unawares. The face I always see now is his face when he was in a rage.'

This information reminded me that her first hysterical symptom, the vomiting, had passed away; the anxiety attack remained and acquired a fresh content. Accordingly, what we were dealing with was a hysteria which had to a considerable extent been abreacted. And in fact she had reported her discovery to her aunt soon after it happened.

'Did you tell your aunt the other stories – about his making advances to you?'

'Yes. Not at once, but later on, when there was already talk of a separation. My aunt said: "We'll keep that in reserve. If he causes trouble in the court, we'll say that too."'

I can well understand that it should have been precisely this last period – when there were more and more agitating scenes in the house and when her own state ceased to interest her aunt, who was entirely occupied with the dispute – that it should have been this period of accumulation and retention that left her the legacy of the mnemic symbol [of the hallucinated face]. [133]

I hope this girl, whose sexual sensibility had been injured at such an early age, derived some benefit from our conversation. I have not seen her since.[1]

DISCUSSION

If someone were to assert that the present case history is not so much an analysed case of hysteria as a case solved by guessing, I should have nothing to say against him. It is true that the patient agreed that what I interpolated into her story was probably true; but she was not in a position to recognize it as something she had experienced. I believe it would have required hypnosis to bring that about. Assuming that my guesses were correct, I will now attempt to fit the case into the schematic picture of an 'acquired' hysteria on the lines suggested by Case 3. It seems plausible, then, to compare the two sets of erotic experiences with 'traumatic' moments and the scene of discovering the couple with an 'auxiliary' moment. [Cf. p. 108 f. above.] The similarity lies in the fact that in the former experiences an element of consciousness was created which was excluded from the thought activity of the ego and remained, as it were, in storage, while in the latter scene a new impression forcibly brought about an associative connection between this separated group and the

1 [Katharina married a local forest manager in September, 1895. They moved to the estates of his employer in Hungary, where she had six children. She returned each summer to the Ottohaus on the Rax, and died there suddenly in 1929.]

ego. On the other hand, there are dissimilarities which cannot be overlooked. The cause of the isolation was not, as in Case 3, an act of will on the part of the ego but *ignorance* on the part of the ego, which was not yet capable of coping with sexual experiences. In this respect the case of Katharina is typical. In every analysis of a case of hysteria based on sexual traumas we find that impressions from the presexual period which produced no effect on the child attain traumatic power at a later date as memories, when the girl or married woman has acquired an understanding of sexual life.[1] The splitting off of psychical groups may be said to be [134] a normal process in adolescent development; and it is easy to see that their later reception into the ego affords frequent opportunities for psychical disturbances. Moreover, I should like at this point to express a doubt as to whether a splitting of consciousness due to ignorance is really different from one due to conscious rejection, and whether even adolescents do not possess sexual knowledge far oftener than is supposed or than they themselves believe.

A further distinction in the psychical mechanism of this case lies in the fact that the scene of discovery, which we have described as 'auxiliary', deserves equally to be called 'traumatic'. It was operative on account of its own content and not merely as something that revived previous traumatic experiences. It combined the characteristics of an 'auxiliary' and a 'traumatic' moment. There seems no reason, however, why this coincidence should lead us to abandon a conceptual separation which in other cases corresponds also to a separation in time. Another peculiarity of Katharina's case, which, incidentally, has long been familiar to us, is seen in the circumstance that the conversion, the production of the hysterical phenomena, did not occur immediately after the trauma but after an interval of incubation. Charcot liked to describe this interval as the 'period of psychical working out' [*élaboration*].[2]

The anxiety from which Katharina suffered in her attacks was a hysterical one; that is, it was a reproduction of the anxiety which had appeared in connection with each of the sexual traumas. I shall not here comment on the fact which I have found regularly present in a very large

1 [This is the phenomenon of '*Nachträglichkeit*' (see *RSE*, **24**, 77–9). Freud discussed it at considerable length in the later sections of Part II of his 1895 'Project' (Freud, 1950*a*), ibid., **1**, and expressed the same view in Section I of his second paper on 'The Neuropsychoses of Defence' (1896*b*), ibid., **3**, 177 *n*. 1. It was not until some years later that he came to recognize the part played in the production of neuroses by sexual impulses already present in early childhood. Cf. the Editors' Note to the *Three Essays* (1905*d*), ibid., **7**, 113–14.]

2 [See Charcot (1888), **1**, 99. Cf. also Breuer's remarks on the subject on p. 190 below.]

number of cases – namely that a mere suspicion of sexual relations calls up the affect of anxiety in virginal individuals.[1] [Cf. p. 112 *n*. 1 above.]

1 [*Footnote added* 1924:] I venture after the lapse of so many years to lift the veil of discretion and reveal the fact that Katharina was not the niece but the daughter of the landlady. The girl fell ill, therefore, as a result of sexual temptations [*Versuchungen*] on the part of her own father. Distortions like the one which I introduced in the present instance should be altogether avoided in reporting a case history. From the point of view of understanding the case, a distortion of this kind is not, of course, a matter of such indifference as would be shifting the scene from one mountain to another. [*Versuchungen* was evidently misread as '*Versuchen*' by Strachey and therefore translated as 'attempts' in the *SE*.]

CASE 5
FRÄULEIN ELISABETH VON R. (*FREUD*)[1]

[135] In the autumn of 1892 I was asked by a doctor I knew[2] to examine a young lady who had been suffering for more than two years from pains in her legs and who had difficulties in walking. When making this request he added that he thought the case was one of hysteria, though there was no trace of the usual indications of that neurosis. He told me that he knew the family slightly and that during the last few years it had met with many misfortunes and not much happiness. First the patient's father had died, then her mother had had to undergo a serious eye operation and soon afterwards a married sister had succumbed to a heart affection of long standing after a confinement. In all these troubles and in all the sick-nursing involved, the largest share had fallen to our patient.

My first interview with this young woman of twenty-four years of age did not help me to make much further progress in understanding the case. She seemed intelligent and mentally normal and bore her troubles, which interfered with her social life and pleasures, with a cheerful air – the *belle indifférence* of a hysteric,[3] I could not help thinking. She walked with the upper part of her body bent forward, but without making use of any support. Her gait was not of any recognized pathological type, and moreover was by no means strikingly bad. All that was apparent was that she complained of great pain in walking and of being quickly overcome by fatigue both in walking and in standing, and that after a short time she had to rest, which lessened the pains but did not do away with them altogether. The pain was of an indefinite character; I gathered that it was something in the nature of a painful fatigue. A fairly large, ill-defined area of the anterior surface of the right thigh was indicated as the focus of the pains, from which they most often radiated and where they reached their greatest intensity. In this area the skin and muscles were also particularly sensitive to pressure and pinching (though the [136] prick of a needle was, if anything, met with a certain amount of unconcern). This hyperalgesia of the skin and muscles was not restricted to this area but could be observed more or less over the whole of both legs. The

1 [This patient was a well-born Hungarian.]

2 [Probably Breuer.]

3 [Freud quotes this phrase again in his paper on repression (1915*d*), where he attributes it to Charcot: *RSE*, **14**, 138.]

muscles were perhaps even more sensitive to pain than the skin; but there could be no question that the thighs were the parts most sensitive to both these kinds of pain. The motor power of the legs could not be described as small, and the reflexes were of medium strength. There were no other symptoms, so that there was no ground for suspecting the presence of any serious organic affection. The disorder had developed gradually during the previous two years and varied greatly in intensity.

I did not find it easy to arrive at a diagnosis, but I decided for two reasons to assent to the one proposed by my colleague [viz. that it was a case of hysteria]. In the first place I was struck by the indefiniteness of all the descriptions of the character of her pains given me by the patient, who was nevertheless a highly intelligent person. A patient suffering from organic pains will, unless he is neurotic in addition, describe them definitely and calmly. He will say, for instance, that they are shooting pains, that they occur at certain intervals, that they extend from this place to that and that they seem to him to be brought on by one thing or another. Again, when a neurasthenic[1] describes his pains, he gives an impression of being engaged on a difficult intellectual task to which his strength is quite unequal. His features are strained and distorted as though under the influence of a distressing affect. His voice grows more shrill and he struggles to find a means of expression. He rejects any description of his pains proposed by the physician, even though it may turn out afterwards to have been unquestionably apt. He is clearly of the opinion that language is too poor to find words for his sensations and that those sensations are something unique and previously unknown, of which it would be quite impossible to give an exhaustive description. For this reason he never tires of constantly adding fresh details, and when he is obliged to break off he is sure to be left with the conviction that he has not succeeded in making himself understood by the physician. All this is because his pains have attracted his whole attention to themselves. Fräulein von R. behaved in quite an opposite way; and we [137]
are driven to conclude that, since she nevertheless attached sufficient importance to her symptoms, her attention must be dwelling on something else, of which the pains were only an accessory phenomenon – probably on thoughts and feelings, therefore, which were connected with them.

But there is a second factor which is even more decisively in favour of this view [*Auffassung*][T] of the pains. If one stimulates an area sensitive

1 (A hypochondriac or a person affected with anxiety neurosis.) [These brackets are the author's.]

to pain in someone with an organic illness or in a neurasthenic, the patient's face takes on an expression of discomfort or physical pain. Moreover, he flinches and draws back from the examination and resists it. In the case of Fräulein von R., however, if one pressed or pinched the hyperalgesic skin and muscles of her legs, her face assumed a peculiar expression, which was one of pleasure [*Lust*][T] rather than pain. She cried out – and I could not help thinking that it was as though she was having a voluptuous tickling sensation – her face flushed, she threw back her head and shut her eyes and her body bent backwards. None of this was very exaggerated but it was distinctly noticeable, and it could only be reconciled with the view that her disorder was hysterical, and that the stimulation had touched upon a hysterogenic[1] zone.

Her expression of face did not fit in with the pain which was ostensibly set up by the pinching of her muscles and skin; it was probably more in harmony with the subject matter of the thoughts which lay concealed behind the pain and which had been aroused in her by the stimulation of the parts of the body associated with those thoughts. I had repeatedly observed expressions of similar significance in undoubted cases of hysteria, when a stimulus was applied to their hyperalgesic zones. Her other gestures were evidently very slight hints of a hysterical attack.

To begin with there was no explanation of the unusual localization of her hysterogenic zone. The fact that the hyperalgesia mainly affected the muscles also gave food for thought. The disorder which is most usually responsible for diffuse and local sensitivity to pressure in the muscles is a rheumatic infiltration of those muscles – common chronic muscular rheumatism. I have already [p. 63 *n.* 1 above] spoken of its tendency to
[138] simulate nervous affections. This possibility was not contradicted by the consistency of the patient's hyperalgesic muscles. There were numerous hard fibres in the muscular substance, and these seemed to be especially sensitive. Thus it was probable that an organic change in the muscles of the kind indicated was present and that the neurosis attached itself to this and made it seem of exaggerated importance.

Treatment proceeded on the assumption that the disorder was of this mixed kind. We recommended the continuation of systematic kneading and faradization of the sensitive muscles, regardless of the resulting pain, and I reserved to myself treatment of her legs with high-tension electric currents, in order to be able to keep in touch with her. Her question whether she should force herself to walk was answered with a decided 'yes'.

1 [So in the first edition. All later editions have, no doubt erroneously, 'hysterical'.]

In this way we brought about a slight improvement. In particular, she seemed to take quite a liking to the painful shocks produced by the high-tension apparatus, and the stronger these were the more they seemed to push her own pains into the background. In the meantime my colleague was preparing the ground for psychical treatment, and when, after four weeks of my pretence treatment, I proposed the other method and gave her some account of its procedure and mode of operation, I met with quick understanding and little resistance.

The task on which I now embarked turned out, however, to be one of the hardest that I had ever undertaken, and the difficulty of giving a report upon it is comparable, moreover, with the difficulties that I had then to overcome. For a long time, too, I was unable to grasp the connection between the events in her illness and her actual symptoms, which must nevertheless have been caused and determined by that set of experiences.

When one starts upon a cathartic treatment of this kind, the first question one asks oneself is whether the patient herself is aware of the origin and the precipitating cause of her illness. If so, no special technique is required to enable her to reproduce the story of her illness. The interest shown in her by the physician, the understanding of her which he allows her to feel and the hopes of recovery he holds out to her – all these will decide the patient to yield up her secret. From the beginning it seemed to me probable that Fräulein Elisabeth was conscious of the [139]
basis of her illness, that what she had in her consciousness was only a secret and not a foreign body. Looking at her, one could not help thinking of the poet's words:

Das Mäskchen da weissagt verborgnen Sinn.[1]

In the first instance, therefore, I was able to do without hypnosis, with the reservation, however, that I could make use of it later if in the course of her confession material arose to the elucidation of which her memory was unequal. Thus it came about that in this, the first full-length analysis of a hysteria undertaken by me, I arrived at a procedure which I later developed into a regular method and employed deliberately. This procedure was one of clearing away the pathogenic psychical material layer by layer, and we liked to compare it with the technique of excavating a buried city. I would begin by getting the patient to tell me what was

1 ['Her mask reveals a hidden sense.' Adapted from Goethe's *Faust*, Part I (Scene 16).] – Nevertheless, it will be seen later that I was mistaken in this.

known to her and I would carefully note the points at which some train of thought remained obscure or some link in the causal chain seemed to be missing. And afterwards I would penetrate into deeper layers of her memories at these points by carrying out an investigation under hypnosis or by the use of some similar technique. The whole work was, of course, based on the expectation that it would be possible to establish a completely adequate set of determinants[t] for the events concerned. I shall discuss presently the methods used for the deep investigation.

The story which Fräulein Elisabeth told of her illness was a wearisome one, made up of many different painful experiences. While she told it she was not under hypnosis; but I made her lie down and keep her eyes shut, though I made no objection to her occasionally opening them, changing her position, sitting up, and so on. When she was more deeply moved than usual by a part of her story she seemed to fall into a state more or less resembling hypnosis. She would then lie motionless and keep her eyes tightly shut.

I will begin by repeating what emerged as the most superficial layer of her memories. The youngest of three daughters, she was tenderly attached to her parents and spent her youth on their estate in Hungary.
[140] Her mother's health was frequently troubled by an affection of the eyes as well as by nervous states. Thus it came about that she found herself drawn into especially intimate contact with her father, a vivacious man of the world, who used to say that this daughter of his took the place of a son and a friend with whom he could exchange thoughts. Although the girl's mind found intellectual stimulation from this relationship with her father, he did not fail to observe that her mental constitution was on that account departing from the ideal which people like to see realized in a girl. He jokingly called her 'cheeky' and 'cocksure', and warned her against being too positive in her judgements and against her habit of regardlessly telling people the truth, and he often said she would find it hard to get a husband. She was in fact greatly discontented with being a girl. She was full of ambitious plans. She wanted to study or to have a musical training, and she was indignant at the idea of having to sacrifice her inclinations and her freedom of judgement by marriage. As it was, she nourished herself on her pride in her father and in the prestige and social position of her family, and she jealously guarded everything that was bound up with these advantages. The unselfishness, however, with which she put her mother and elder sisters first, when an occasion arose, reconciled her parents completely to the harsher side of her character.

In view of the girls' ages it was decided that the family should move to the capital, where Elisabeth was able for a short time to enjoy a fuller and gayer life in the home circle. Then, however, the blow fell which destroyed the happiness of the family. Her father had concealed, or had perhaps himself overlooked, a chronic affection of the heart, and he was brought home unconscious one day suffering from a pulmonary oedema. He was nursed for eighteen months, and Elisabeth saw to it that she played the leading part at his sick-bed. She slept in his room, was ready to wake if he called her at night, looked after him during the day and forced herself to appear cheerful, while he reconciled himself to his hopeless state with uncomplaining resignation. The beginning of her illness must have been connected with this period of nursing, for she remembered that during its last six months she had taken to her bed for a day and a half on account of the pains we have described. She asserted, however, that these pains quickly passed off and had not caused her any uneasiness or attracted her attention. And, in fact, it was not until two [141] years after her father's death that she felt ill and became incapable of walking on account of her pains.

The gap that was caused in the life of this family of four women by her father's death, their social isolation, the breaking off of so many connections that had promised to bring her interest and enjoyment, her mother's ill-health which was now becoming more marked – all this cast a shadow over the patient's state of feeling; but at the same time it kindled a lively desire in her that her family might soon find something to replace their lost happiness, and led her to concentrate her whole affection and care on the mother who was still living.

When the year of mourning had passed, her elder sister married a gifted and energetic man. He occupied a responsible position and his intellectual powers seemed to promise him a great future. But to his closer acquaintances he exhibited a morbid sensitiveness and an egoistic insistence on his fads; and he was the first in the family circle to venture to show lack of consideration for the old lady. This was more than Elisabeth could bear. She felt called upon to take up the fight against her brother-in-law whenever he gave her occasion, while the other women did not take his temperamental outbursts to heart. It was a painful disappointment to her that the rebuilding of their former family happiness should be thus interrupted; and she could not forgive her married sister for the feminine pliancy with which she persistently avoided taking sides. Elisabeth retained a number of scenes in her memory in this connection, involving complaints, in part not expressed in words, against

her first brother-in-law. But her chief reproach against him remained the fact that, for the sake of a prospective promotion, he moved with his small family to a remote town in Austria and thus helped to increase her mother's isolation. On this occasion Elisabeth felt acutely her helplessness, her inability to afford her mother a substitute for the happiness she had lost and the impossibility of carrying out the intention she had formed at her father's death.

The marriage of her second sister seemed to promise a brighter future for the family, for the second brother-in-law, though less outstanding intellectually, was a man after the heart of these cultivated women, brought up as they had been in a school of consideration for others. His
[142] behaviour reconciled Elisabeth to the institution of marriage and to the thought of the sacrifices it involved. Moreover, the second young couple remained in her mother's neighbourhood, and their child became Elisabeth's favourite. Unfortunately, another event cast a shadow over the year in which this child was born. The treatment of her mother's eye trouble necessitated her being kept in a dark room for several weeks, during which Elisabeth was with her. An operation was then pronounced unavoidable. The agitation at this prospect coincided with the preparations for her first brother-in-law's move. At last her mother came through the operation, which was performed by a master hand. The three families were united at a summer holiday resort, and it was hoped that Elisabeth, who had been exhausted by the anxieties of the last few months, would make a complete recovery during what was the first period of freedom from sorrows and fears that the family had enjoyed since her father's death.

It was precisely during this holiday, however, that Elisabeth's pains and locomotor weakness started. She had been to some extent aware of the pains for a short while, but they came on violently for the first time after she had had a warm bath in the bath establishment of the little watering place. A few days earlier she had been for a long walk – in fact, a regular tramp lasting half a day – and this they connected with the appearance of the pains, so that it was easy to take the view that Elisabeth had first been 'overtired' and had then 'caught cold'.

From this time on Elisabeth was the invalid of the family. She was advised by her doctor to devote the rest of the same summer to a course of hydropathic treatment at Gastein [in the Austrian Alps], and she went there with her mother. But a fresh anxiety now arose. Her second sister had become pregnant again and reports of her condition were most unfavourable, so that Elisabeth could hardly make up her mind to travel

to Gastein. She and her mother had been there for barely a fortnight when they were called back by the news that her sister, who had now taken to her bed, was in a very bad state.

There followed an agonizing journey, during which Elisabeth was tormented not only by her pains but by dreadful expectations; on their arrival at the station there were signs that led them to fear the worst; and when they entered the sick-room there came the certainty that they had come too late to take their leave of a living person. [143]

Elisabeth suffered not only from the loss of this sister, whom she had dearly loved, but almost as much from the thoughts provoked by her death and the changes which it brought along with it. Her sister had succumbed to an affection of the heart which had been aggravated by her pregnancy. The idea now presented itself that heart disease was inherited from the father's side of the family. It was then recalled that the dead sister had suffered during her early girlhood from chorea accompanied by a mild cardiac disorder. They blamed themselves and the doctors for having permitted the marriage, and it was impossible to spare the unhappy widower the reproach of having endangered his wife's health by bringing on two pregnancies in immediate succession. From that time onwards Elisabeth's thoughts were occupied without interruption with the gloomy reflection that when, for once in a way, the rare conditions for a happy marriage had been fulfilled, this happiness should have come to such an end. Furthermore, she saw the collapse once more of all she had desired for her mother. Her widowed brother-in-law was inconsolable and withdrew from his wife's family. It appeared that his own family, which had been estranged from him during his short, happy marriage, thought this was a favourable moment for drawing him back into their own circle. There was no way of preserving the unity that had existed formerly. It was not practicable for him to live with her mother in view of Elisabeth's unmarried state. Since, also, he refused to allow the two women to have the custody of the child, which was the dead woman's only legacy, he gave them occasion for the first time to accuse him of hard-heartedness. Lastly – and this was not the least distressing fact – a rumour reached Elisabeth that a dispute had arisen between her two brothers-in-law. She could only guess at its cause; it seemed, however, that the widower had put forward financial demands which the other declared were unjustifiable and which, indeed, in view of the mother's present sorrow, he was able to characterize as blackmail of the worst description.

Here, then, was the unhappy story of this proud girl with her longing

for love. Unreconciled to her fate, embittered by the failure of all her little schemes for re-establishing the family's former glories, with those
[144] she loved dead or gone away or estranged, unready to take refuge in the love of some unknown man – she had lived for eighteen months in almost complete seclusion, with nothing to occupy her but the care of her mother and her own pains.

If we put greater misfortunes on one side and enter into a girl's feelings, we cannot refrain from deep human sympathy with Fräulein Elisabeth. But what shall we say of the purely medical interest of this tale of suffering, of its relations to her painful locomotor weakness, and of the chances of an explanation and cure afforded by our knowledge of these psychical traumas?

As far as the physician was concerned, the patient's confession was at first sight a great disappointment. It was a case history made up of commonplace emotional upheavals, and there was nothing about it to explain why it was particularly from hysteria that she fell ill or why her hysteria took the particular form of a painful abasia. It threw light on neither the causes nor the specific determination of her hysteria. We might perhaps suppose that the patient had formed an association between her painful mental impressions and the bodily pains which she happened to be experiencing at the same time, and that now, in her life of memories, she was using her physical feelings as a symbol of her mental ones. But it remained unexplained what her motives might have been for making a substitution of this kind and at what moment it had taken place. These, incidentally, were not the kinds of questions that physicians were in the habit of raising. We were usually content with the statement that the patient was constitutionally a hysteric, liable to develop hysterical symptoms under the pressure of intense excitations *of whatever kind*.

Her confession seemed to offer even less help towards the cure of her illness than it did towards its explanation. It was not easy to see what beneficent influence Fräulein Elisabeth could derive from recapitulating the tale of her sufferings of recent years – with which all the members of her family were so familiar – to a stranger who received it with only a moderate sympathy. Nor was there any sign of the confession producing a curative effect of this kind. During this first period of her treatment she never failed to repeat that she was still feeling ill and that her pains were as bad as ever; and, when she looked at me as she said this with a
[145] sly look of satisfaction at my discomfiture, I could not help being reminded of old Herr von R.'s judgement about his favourite daughter – that she was often 'cheeky' and 'ill behaved'. But I was obliged to admit that she was in the right.

If I had stopped the patient's psychical treatment at this stage, the case of Fräulein Elisabeth von R. would clearly have thrown no light on the theory of hysteria. But I continued my analysis because I firmly expected that deeper levels of her consciousness would yield an understanding both of the causes and the specific determinants of the hysterical symptoms. I therefore decided to put a direct question to the patient in an enlarged state of consciousness and to ask her what psychical impression it had been to which the first emergence of pains in her legs had been attached.

With this end in view I proposed to put the patient into a deep hypnosis. But, unfortunately, I could not help observing that my procedure failed to put her into any state other than the one in which she had made her recital. I was glad enough that on this occasion she refrained from triumphantly protesting: 'I'm not asleep, you know; I can't be hypnotized.' In this extremity the idea occurred to me of resorting to the device of applying pressure to the head, the origin of which I have described in full in the case history of Miss Lucy [p. 97 ff. above]. I carried this out by instructing the patient to report to me faithfully whatever appeared before her inner eye or passed through her memory at the moment of the pressure. She remained silent for a long time and then, on my insistence, admitted that she had thought of an evening on which a young man had seen her home after a party, of the conversation that had taken place between them and of the feelings with which she had returned home to her father's sick-bed.

This first mention of the young man opened up a new vein of ideas the contents of which I now gradually extracted. It was a question here of a secret, for she had initiated no-one, apart from a common friend, into her relations with the young man and the hopes attached to them. He was the son of a family with which they had long been on friendly terms and who lived near their former estate. The young man, who was himself an orphan, was devotedly attached to her father and followed his advice in pursuing his career. He had extended his admiration for [146]
her father to the ladies of the family. Numerous recollections of reading together, of exchanging ideas, and of remarks made by him which were repeated to her by other people, bore witness to the gradual growth in her of a conviction that he loved her and understood her and that marriage with him would not involve the sacrifices on her part which she dreaded from marriage in general. Unluckily, he was scarcely any older than herself and was still far from being self-supporting. But she was firmly determined to wait for him.

After her father had fallen seriously ill and she had been so much taken up with looking after him, her meetings with her friend became more and more rare. The evening which she had first remembered represented what had actually been the climax of her feeling; but even then there had been no *éclaircissement* between them. On that occasion she had allowed herself to be persuaded, by the insistence of her family and of her father himself, to go to a party at which she was likely to meet him. She had wanted to hurry home early but had been pressed to stay and had given way when he promised to see her home. She had never had such warm feelings towards him as while he was accompanying her that evening. But when she arrived home late in this blissful frame of mind, she found her father was worse and reproached herself most bitterly for having sacrificed so much time to her own enjoyment. This was the last time she left her sick father for a whole evening. She seldom met her friend after this. After her father's death the young man seemed to keep away from her out of respect for her sorrow. The course of his life then took him in other directions. She had to familiarize herself by degrees with the thought that his interest in her had been displaced by others and that she had lost him. But this disappointment in her first love still hurt her whenever she thought of him.

It was therefore in this relationship and in the scene described above in which it culminated that I could look for the causes of her first hysterical pains. The contrast between the blissful feelings she had allowed herself to enjoy on that occasion and the worsening of her father's state which had met her on her return home constituted a conflict, a situation of incompatibility. The outcome of this conflict was that the erotic idea was repressed from association and the affect attaching to that idea was
[147] used to intensify or revive a physical pain which was present simultaneously or shortly before. Thus it was an instance of the mechanism of conversion for the purpose of defence [*Abwehr*][T], which I have described in detail elsewhere.[1]

A number of comments might of course be made at this point. I must emphasize the fact that I did not succeed in establishing from her memory that the conversion took place at the moment of her return home. I therefore looked about for similar experiences during the time she was nursing her father and elicited a number of them. Among these, special prominence attached, on account of their frequent occurrence, to scenes in which, at her father's call, she had jumped out of bed with

1 [See Freud's first paper on 'The Neuropsychoses of Defence' (1894*a*), *RSE*, **3**, 46 ff., and the footnote on p. 9 above.]

bare feet in a cold room. I was inclined to attribute some importance to these factors, since in addition to complaining about the pain in her legs she also complained of tormenting sensations of cold. Nevertheless, even here I was unable to get hold of any scene which it was possible to identify as that at which the conversion had occurred. I was inclined for this reason to think that there was a gap in the explanation at this point, until I recollected that the hysterical pains in the legs had in fact not made their appearance during the period when she was nursing her father. She remembered only a single attack of pain, which had lasted only a day or two and had not attracted her attention [p. 125 above]. I now directed my enquiries to this first appearance of the pains. I succeeded in reviving the patient's memory of it with certainty. At that very time a relative had visited them and she had been unable to receive him, owing to being laid up in bed. This same man had been unlucky enough, when he visited them again two years later, to find her in bed once more. But in spite of repeated attempts we failed to trace any psychical cause for the first pains. I thought it safe to assume that they had in fact appeared without any psychical cause and were a mild rheumatic affection; and I was able to establish that this organic disorder, which was the model copied in her later hysteria, had in any case to be dated before the scene of her being accompanied back from the party. From the nature of things it is nevertheless possible that these pains, being of organic origin, may have persisted for some time to a mitigated degree without being very noticeable. The obscurity due to the fact that the analysis pointed to the occurrence of a conversion of psychical excitation into physical pain though that pain was certainly not perceived at the time in question or remembered afterwards – this is a problem which I hope to be able to solve later on the basis of further considerations and later examples.[1] [See below, p. 149 ff.] [148]

The discovery of the reason [*Motivs*][T] for the first conversion opened a second, fruitful period of the treatment. The patient surprised me soon afterwards by announcing that she now knew why it was that the pains always radiated from that particular area of the right thigh and were at their most painful there: it was in this place that her father used to rest his leg every morning, while she renewed the bandage round it, for it was badly swollen. This must have happened a good hundred times, yet she had not noticed the connection till now. In this way she

1 I cannot exclude the possibility, though I cannot establish the fact, that these pains, which chiefly affected the thighs, were of a *neurasthenic* nature. [Cf. p. 155 *n*. below.]

gave me the explanation that I needed of the emergence of what was an atypical hysterogenic zone. Further, her painful legs began to 'join in the conversation' [*mitzusprechen*] during our analyses. [See p. 264 below.] What I have in mind is the following remarkable fact. As a rule the patient was free from pain when we started work. If, then, by a question or by pressure upon her head I called up a memory, a sensation of pain would make its first appearance, and this was usually so sharp that the patient would give a start and put her hand to the painful spot. The pain that was thus aroused would persist so long as she was under the influence of the memory; it would reach its climax when she was in the act of telling me the essential and decisive part of what she had to communicate, and with the last word of this it would disappear. I came in time to use such pains as a compass to guide me; if she stopped talking but admitted that she still had a pain, I knew that she had not told me everything, and insisted on her continuing her story till the pain had been talked away. Not until then did I arouse a fresh memory.

During this period of 'abreaction' the patient's condition, both physical and mental, made such a striking improvement that I used to say, only half-jokingly, that I was taking away a certain amount of her [149] motives for pain [*Schmerzmotiven*] every time and that when I had cleared them all away she would be well. She soon got to the point of being without pain most of the time; she allowed herself to be persuaded to walk about a great deal and to give up her former isolation. In the course of the analysis I sometimes followed the spontaneous fluctuations in her condition; and I sometimes followed my own estimate of the situation when I considered that I had not completely exhausted some portion of the story of her illness.

During this work I made some interesting observations, whose lessons I subsequently found confirmed in treating other patients. As regards the spontaneous fluctuations, in the first place, I found that in fact none had occurred which had not been provoked by association with some contemporary event. On one occasion she had heard of an illness of one of her acquaintances which reminded her of a detail of her father's illness; another time her dead sister's child had been on a visit to them, and its likeness to its mother had stirred up her feelings of grief; and yet another time a letter from her distant sister showed clear evidence of her unfeeling brother-in-law's influence and gave rise to a pain which required her to produce the story of a family scene which she had not yet told me about. Since she never brought up the same precipitating cause of a pain twice over, it seemed that we were justified in supposing

that we should in this way exhaust the stock of them; and I therefore did not hesitate to get her into situations which were calculated to bring up fresh memories which had not yet reached the surface. For instance, I sent her to visit her sister's grave, and I encouraged her to go to a party at which she might once more come across the friend of her youth.

In the next place, I obtained some insight into the manner of origin of what might be described as a 'monosymptomatic' hysteria. For I found that her *right* leg became painful under hypnosis when the discussion turned on her nursing her sick father, on her relations with the friend of her youth or on other events falling within the first period of her pathogenic experiences; on the other hand, the pain made its appearance in her other, *left*, leg as soon as I stirred up a memory relating to her dead sister or her two brothers-in-law – in short, to an impression from the second half of the story of her illness. Having thus had my attention aroused by the regularity of this relation, I carried my investigation further and formed an impression that this differentiation went still further and that every fresh psychical determinant of painful sensations had become attached to some fresh spot in the painful area of her legs. The original painful spot in her right thigh had related to her nursing her father; the area of pain had extended from this spot to neighbouring regions as a result of fresh traumas. Here, therefore, what we were dealing with was not strictly speaking a *single* physical symptom, linked with a variety of mnemic complexes in the mind, but a number of similar symptoms which appeared, on a superficial view, to be merged into one symptom. But I did not pursue further the delimitation of zones of pain corresponding to different psychical determinants, since I found that the patient's attention was directed away from this subject. [150]

I did, however, turn my attention to the way in which the whole symptomatic complex of abasia might have been built up upon these painful zones, and in that connection I asked her various questions, such as what was the origin of her pains in walking? in standing? and in lying down? Some of these questions she answered spontaneously, some under the pressure of my hand. Two things emerged from this. In the first place she divided all the scenes with painful impressions attached to them into groups for me, according as she had experienced them while she was sitting or standing, and so on. For instance, she was *standing* by a door when her father was brought home with his heart attack [p. 125 above], and in her fright she stood stock still as though she was rooted to the ground. She went on to add a number of other memories to this first example of fright while she was standing, till she came to the

fearful scene in which once again she *stood*, as though spellbound, by her sister's deathbed [p. 127 above]. This whole chain of memories might be expected to show that there was a legitimate connection between her pains and standing up; and it might indeed be accepted as evidence of an association. But we must bear in mind that another factor must be proved to be present in all these events, one which directed her attention precisely to her standing (or, as the case may be, to her walking, sitting, etc.) and consequently led to conversion. The explanation of her attention taking this direction can scarcely be looked for elsewhere than
[151] in the circumstance that walking, standing and lying are functions and states of those parts of her body which in her case comprised the painful zones, namely, her legs. It was therefore easy in the present case to understand the connection between the astasia-abasia and the first occurrence of conversion.

Among the episodes which, according to this catalogue, seemed to have made *walking* painful, one received special prominence: a walk which she had taken at the health resort in the company of a number of other people [p. 126 above] and which was supposed to have been too long. The details of this episode only emerged with hesitation and left several riddles unsolved. She had been in a particularly yielding mood, and eagerly joined her party of friends. It was a fine day, not too hot. Her mother stopped at home and the elder sister had already gone away. The younger sister felt unwell, but did not want to spoil her enjoyment; the brother-in-law began by saying that he would stay with his wife, but afterwards decided to join the party on Elisabeth's account. This scene seemed to have had a great deal to do with the first appearance of the pains, for she remembered being very tired and suffering from violent pain when she returned from the walk. She said, however, that she was not certain whether she had already noticed the pains before this. I pointed out to her that she was unlikely to have undertaken such a long walk if she had had any considerable pains. I asked her what it was in the walk that might have brought on the pain and she gave me the somewhat obscure reply that the contrast between her own loneliness and her sick sister's married happiness (which her brother-in-law's behaviour kept constantly before her eyes) had been painful to her.

Another scene, which was very close to the former one in time, played a part in linking the pains with *sitting*. It was a few days later. Her sister and brother-in-law had already left the place. She found herself in a restless, yearning mood. She rose early in the morning and climbed a small hill to a spot which they had often been to together and which

afforded a lovely view. She sat down there on a stone bench and gave herself up to her thoughts. These were once again concerned with her loneliness and the fate of her family; and this time she openly confessed to a burning wish that she might be as happy as her sister. She returned from this morning meditation with violent pains, and that same evening had the bath after which the pains made their final and permanent [152]
appearance [p. 126 above].

It was further shown without any doubt that her pain in walking and standing used, to begin with, to be allayed when she was *lying down*. The pains were not linked to lying down as well until, after hearing the news of her sister's illness, she travelled back from Gastein [loc. cit.] and was tormented during the night alike by worry about her sister and by raging pains, as she lay, sleepless, stretched out in the railway carriage. And for quite a time after this, lying down was actually more painful to her than walking or standing.

In this way, firstly, the painful region had been extended by the addition of adjacent areas: every fresh theme which had a pathogenic effect had cathected a new region in the legs; secondly, each of the scenes which made a powerful impression on her had left a trace behind it, bringing about lasting and constantly accumulating 'cathexis' of the various functions of the legs, a linking of these functions with her feelings of pain. But a third mechanism had unmistakably been involved in the building up of her astasia-abasia. The patient ended her description of a whole series of episodes by complaining that they had made the fact of her 'standing alone' painful to her. In another series of episodes, which comprised her unsuccessful attempts to establish a new life for her family, she never tired of repeating that what was painful about them had been her feeling of helplessness, the feeling that she could not 'take a single step forward'. In view of this, I was forced to suppose that among the influences that went to the building up of her abasia, these reflections of hers played a part; I could not help thinking that the patient had done nothing more nor less than look for a *symbolic* expression of her painful thoughts and that she had found it in the intensification of her sufferings. The fact that somatic symptoms of hysteria can be brought about by symbolization of this kind was already asserted in our 'Preliminary Communication' [p. 5 above]. In the Discussion on the present case I shall bring forward two or three conclusive instances of this. [See p. 156 ff. below.] This psychical mechanism of symbolization did not play a prominent part with Fräulein Elisabeth von R. It did not *create* her abasia. But everything goes to show that the

abasia which was already present received considerable reinforcement
[153] in this way. Accordingly, this abasia, at the stage of development at which I came across it, was to be equated not only with a functional paralysis based on psychical associations but also with one based on symbolization.

Before I resume my account of the case I will add a few words on the patient's behaviour during this second phase of the treatment. Throughout the analysis I made use of the technique of bringing out pictures and ideas by means of pressing on the patient's head, a method, that is, which would be unworkable without the patient's full cooperation and willing attention. [Cf. p. 97 f. above.] Sometimes, indeed, her behaviour fulfilled my highest expectations, and during such periods it was surprising with what promptitude the different scenes relating to a given theme emerged in a strictly chronological order. It was as though she were reading a lengthy book of pictures, whose pages were being turned over before her eyes. At other times there seemed to be impediments of whose nature I had no suspicion then. When I pressed her head she would maintain that nothing occurred to her. I would repeat my pressure and tell her to wait, but still nothing appeared. The first few times when this recalcitrance exhibited itself I allowed myself to be led into breaking off the work: it was an unfavourable day; we would try another time. Two observations, however, decided me to alter my attitude. I noticed, in the first place, that the method failed in this way only when I found Elisabeth in a cheerful state and free from pain, never when she was feeling badly. In the second place, that she often made such assertions as that she saw nothing, after she had allowed a long interval to pass during which her tense and preoccupied expression of face nevertheless betrayed the fact that a mental process was taking place in her. I resolved, therefore, to adopt the hypothesis that the procedure never failed: that on every occasion under the pressure of my hand some idea occurred to Elisabeth or some picture came before her eyes, but that she was not always prepared to communicate it to me, and tried to suppress once more what had been conjured up. I could think of two motives for this concealment. Either she was applying criticism to the idea, which she had no right to do, on the ground of its not being important enough or of its being an irrelevant reply to the question she had been asked; or she hesitated to produce it because – she found it too disagreeable to tell. I therefore proceeded as though I was com-
[154] pletely convinced of the trustworthiness of my technique. I no longer accepted her declaration that nothing had occurred to her, but assured

her that something *must* have occurred to her. Perhaps, I said, she had not been sufficiently attentive, in which case I should be glad to repeat my pressure. Or perhaps she thought that her idea [*Einfall*] was not the right one. This, I told her, was not her affair; she was under an obligation to remain completely objective and say what had come into her head, whether it was appropriate or not. Finally, I declared that I knew very well that something *had* occurred to her and that she was concealing it from me; but she would never be free of her pains so long as she concealed anything. By thus insisting, I brought it about that from that time forward my pressure on her head never failed in its effect. I could not but conclude that I had formed a correct opinion of the state of affairs, and I derived from this analysis a literally unqualified reliance on my technique. It often happened that it was not until I had pressed her head three times that she produced a piece of information; but she herself would remark afterwards: 'I could have said it to you the first time.' – 'And why didn't you?' – 'I thought it wasn't what was wanted', or 'I thought I could avoid it, but it came back each time.' In the course of this difficult work I began to attach a deeper significance to the resistance [*Widerstande*] offered by the patient in the reproduction of her memories and to make a careful collection of the occasions on which it was particularly marked.[1]

I have now arrived at the third period of the treatment. The patient was better. She had been mentally relieved and was now capable of successful effort. But her pains had manifestly not been removed; they recurred from time to time, and with all their old severity. This incomplete therapeutic result corresponded to an incompleteness in the analysis. I still did not know exactly at what moment and by what mechanism the pains had originated. During the reproduction of the great variety of scenes in the second period and while I was observing the patient's resistance to telling me about them, I had formed a particular suspicion. I did not venture yet, however, to adopt it as the basis of my further action. But a chance occurrence decided the matter. One day while I was working [155] with the patient, I heard a man's footsteps in the next room and a pleasant voice which seemed to be asking some question. My patient thereupon got up and asked that we might break off for the day: she had heard her brother-in-law arrive and enquire for her. Up to that point she had been free from pain, but after the interruption her facial expression and gait betrayed the sudden emergence of severe pains. My

1 [This is the first mention of the important clinical fact of 'resistance'. It is discussed at greater length below, p. 238 ff.]

suspicion was strengthened by this and I determined to precipitate the decisive explanation.

I therefore questioned her about the causes and circumstances of the first appearance of the pains. By way of answer her thoughts turned towards her summer visit to the health resort before her journey to Gastein, and a number of scenes turned up once more which had not been treated very completely. She recalled her state of feeling at the time, her exhaustion after her anxieties about her mother's eyesight and after having nursed her at the time of her operation, and her final despair of a lonely girl like her being able to get any enjoyment out of life or achieve anything in it. Till then she had thought herself strong enough to be able to do without the help of a man; but she was now overcome by a sense of her weakness as a woman and by a longing for love in which, to quote her own words, her frozen nature began to melt. In this mood she was deeply affected by her second sister's happy marriage – by seeing with what touching care he looked after her, how they understood each other at a single glance and how sure they seemed to be of each other. It was no doubt to be regretted that the second pregnancy followed so soon after the first, and her sister knew that this was the reason for her illness; but how willingly she bore it because he was its cause. On the occasion of the walk which was so intimately connected with Elisabeth's pains, her brother-in-law had at first been unwilling to join in it and had wanted to stay by his sick wife. She, however, persuaded him with a look to go with them, because she thought it would give Elisabeth pleasure. Elisabeth remained in his company all through the walk. They discussed every kind of subject, among them the most intimate ones. She found herself in complete agreement with everything he said, and a desire to have a husband like him became very strong in her. Then, a few days later, came the scene on the morning after the
[156] departure of her sister and brother-in-law when she made her way to the place with a view, which had been a favourite object of their walks. There she sat down and dreamt once again of enjoying such happiness as her sister's and of finding a husband who would know how to capture her heart like this brother-in-law of hers. She was in pain when she stood up, but it passed off once more. It was not until the afternoon, when she had had the warm bath, that the pains broke out, and she was never again free from them. I tried to discover what thoughts were occupying her mind while she was having the bath; but I learnt only that the bath-house had reminded her of the members of her family who had gone away, because that was the building in which they had stayed.

It had inevitably become clear to me long since what all this was about; but the patient, deep in her bitter-sweet memories, seemed not to notice the end to which she was steering, and continued to reproduce her recollections. She went on to her visit to Gastein, the anxiety with which she looked forward to every letter, finally the bad news about her sister, the long wait till the evening, which was the first moment at which they could get away from Gastein, then the journey, passed in tormenting uncertainty, and the sleepless night – all of these accompanied by a violent increase in her pains. I asked her whether during the journey she had thought of the grievous possibility which was afterwards realized. She answered that she had carefully avoided the thought, but she believed that her mother had from the beginning expected the worst. – Her memories now went on to their arrival in Vienna, the impression made on them by the relatives who met them, the short journey from Vienna to the summer resort in its neighbourhood where her sister lived, their reaching there in the evening, the hurried walk through the garden to the door of the small garden house, the silence within and the oppressive darkness; how her brother-in-law was not there to receive them, and how they stood before the bed and looked at her sister as she lay there dead. At that moment of dreadful certainty that her beloved sister was dead without bidding them farewell and without her having eased her last days with her care – at that very moment another thought had shot through Elisabeth's mind, and now forced itself irresistibly upon her once more, like a flash of lightning in the dark: 'Now he is free again and I can be his wife.'

Everything was now clear. The analyst's labours were richly rewarded. [157]
The concepts of the 'fending off' [*Abwehr*] of an incompatible idea, of the genesis of hysterical symptoms through the conversion of psychical excitations [*Erregung*] into something physical and the formation [*Bildung*] of a separate psychical group through the act of will which led to the fending off – all these things were, in that moment, brought before my eyes in concrete form. Thus and in no other way had things come about in the present case. This girl felt towards her brother-in-law a tenderness whose acceptance into consciousness was resisted by her whole moral being. She succeeded in sparing herself the painful conviction that she loved her sister's husband, by inducing physical pains in herself instead; and it was in the moments when this conviction sought to force itself upon her (on her walk with him, during her morning reverie, in the bath, by her sister's bedside) that her pains had come on, thanks to successful conversion. At the time when I started her

treatment the group of ideas relating to her love had already been separated from her knowledge. Otherwise she would never, I think, have agreed to embarking on the treatment. The resistance with which she had repeatedly met the reproduction of scenes which operated traumatically corresponded in fact to the energy with which the incompatible idea had been forced out of her associations [*Assoziation*][T].

The period that followed, however, was a hard one for the physician. The recovery of this repressed idea had a shattering effect on the poor girl. She cried aloud when I put the situation drily before her with the words: 'So for a long time you had been in love with your brother-in-law.' She complained at this moment of the most frightful pains, and made one last desperate effort to reject the explanation: it was not true, I had talked her into it, it *could* not be true, she was incapable of such wickedness, she could never forgive herself for it. It was easy to prove to her that what she herself had told me admitted of no other interpretation. But it was a long time before my two pieces of consolation – that we are not responsible for our feelings, and that her behaviour, the fact that she had fallen ill in these circumstances, was sufficient evidence of her moral character – it was a long time before these consolations of mine made any impression on her.

In order to mitigate the patient's sufferings I had now to proceed along
[158] more than one path. In the first place I wanted to give her an opportunity of getting rid of the excitation that had been piling up so long, by 'abreacting' it. We probed into the first impressions made on her in her relations with her brother-in-law, the beginning of the feelings for him which she had kept unconscious. Here we came across all the little premonitory signs and intuitions of which a fully grown passion can make so much in retrospect. On his first visit to the house he had taken her for the girl he was to marry and had greeted her before her elder but somewhat insignificant-looking sister. One evening they were carrying on such a lively conversation together and seemed to be getting on so well that his fiancée had interrupted them half-seriously with the remark: 'The truth is, you two would have suited each other splendidly.' Another time, at a party where they knew nothing of his engagement, the young man was being discussed and a lady criticized a defect in his figure which suggested that he had had a disease of the bones in his childhood. His fiancée herself listened quietly, but Elisabeth flared up and defended the symmetry of her future brother-in-law's figure with a zeal which she herself could not understand. As we worked through these recollections it became clear to Elisabeth that her tender feeling for her brother-in-law

had been dormant in her for a long time, perhaps even from the beginning of her acquaintance with him, and had lain concealed all that time behind the mask of mere sisterly affection, which her highly developed family feeling could enable her to accept as natural.

This process of abreaction certainly did her much good. But I was able to relieve her still more by taking a friendly interest in her present circumstances. With this end in view I arranged for an interview with Frau von R. I found her an understanding and sensitive lady, though her vital spirits had been reduced by her recent misfortunes. I learnt from her that on closer examination the charge of unfeeling blackmail which had been brought by the elder brother-in-law against the widower and which had been so painful to Elisabeth had had to be withdrawn. No stain was left on the young man's character. It was a misunderstanding due to the different value which, as can readily be seen, would be attached to money by a businessman, to whom money is a tool of his trade, and a civil servant. Nothing more than this remained of the painful episode. I begged her mother from that time forward to tell Elisabeth everything she needed to know, and in the future to give [159] her the opportunity for unburdening her mind to which I should have accustomed her.

I was also, of course, anxious to learn what chance there was that the girl's wish, of which she was now conscious, would come true. Here the prospects were less favourable. Her mother told me that she had long ago guessed Elisabeth's fondness for the young man, though she had not known that the feeling had already been there during her sister's lifetime. No-one seeing the two of them together – though in fact this had now become a rare event – could doubt the girl's anxiety to please him. But, she told me, neither she (the mother) nor the family advisers were particularly in favour of a marriage. The young man's health was by no means good and had received a fresh setback from the death of his beloved wife. It was not at all certain, either, that his mental state was yet sufficiently recovered for him to contract a new marriage. This was perhaps why he was behaving with so much reserve; perhaps, too, it was because he was uncertain of his reception and wished to avoid comments that were likely to be made. In view of these reservations on both sides, the solution for which Elisabeth longed was unlikely to be achieved.

I told the girl what I had heard from her mother and had the satisfaction of benefiting her by giving her the explanation of the money affair. On the other hand, I encouraged her to face with calmness the

uncertainty about the future which it was impossible to clear up. But at this point the approach of summer made it urgent for us to bring the analysis to an end. Her condition was once more improved and there had been no more talk of her pains since we had been investigating their causes. We both had a feeling that we had come to a finish, though I told myself that the abreaction of the love she had so long kept down had not been carried out very fully. I regarded her as cured and pointed out to her that the solution to her difficulties would proceed on its own account now that the path had been opened to it. This she did not dispute. She left Vienna with her mother to meet her eldest sister and her family and to spend the summer together.

I have a few words to add upon the further course of Fräulein Elisabeth von R.'s case. Some weeks after we had separated I received
[160] a despairing letter from her mother. At her first attempt, she told me, to discuss her daughter's affairs of the heart with her, the girl had rebelled violently and had since then suffered from severe pains once more. She was indignant with me for having betrayed her secret. She was entirely inaccessible, and the treatment had been a complete failure. What was to be done now? she asked. Elisabeth would have nothing more to do with me. I did not reply to this. It stood to reason that Elisabeth after leaving my care [*Zucht*][t] would make one more attempt to reject her mother's intervention and once more take refuge in isolation. But I had a kind of conviction that everything would come right and that the trouble I had taken had not been in vain. Two months later they were back in Vienna, and the colleague to whom I owed the introduction of the case gave me news that Elisabeth felt perfectly well and was behaving as though there was nothing wrong with her, though she still suffered occasionally from slight pains. Several times since then she has sent me similar messages and each time promised to come and see me. But it is a characteristic of the personal relationship which arises in treatments of this kind that she has never done so. As my colleague assures me, she is to be regarded as cured. Her brother-in-law's connection with the family has remained unaltered.

In the spring of 1894 I heard that she was going to a private ball for which I was able to get an invitation, and I did not allow the opportunity to escape me of seeing my former patient whirl past in a lively dance. Since then, by her own inclination, she has married someone unknown to me.[1]

1 [Elisabeth von R. remained happily married, but later made deprecating remarks about Freud to her daughter and denied having been in love with her brother-in-law (Gay, 1988, 72).]

DISCUSSION

I have not always been a psychotherapist. Like other neuropathologists, I was trained to employ local diagnoses and electro-prognosis, and it still strikes me myself as strange that the case histories I write should read like short stories and that, as one might say, they lack the serious stamp of science. I must console myself with the reflection that the nature of the subject is evidently responsible for this, rather than any preference of my own. The fact is that local diagnosis and electrical reactions lead nowhere in the study of hysteria, whereas a detailed description of mental processes such as we are accustomed to find in the works of imaginative writers enables me, with the use of a few psychological formulas, to obtain at least some kind of insight into the course of that affection. Case histories of this kind are intended to be judged like psychiatric ones; they have, however, one advantage over the latter, namely an intimate connection between the story of the patient's sufferings and the symptoms of his illness – a connection for which we still search in vain in the biographies of other psychoses. [161]

In reporting the case of Fräulein Elisabeth von R. I have endeavoured to weave the explanations which I have been able to give of the case into my description of the course of her recovery. It may perhaps be worthwhile to bring together the important points once more. I have described the patient's character, the features which one meets with so frequently in hysterical people and which there is no excuse for regarding as a consequence of degeneracy: her giftedness, her ambition, her moral sensibility, her excessive demand for love which, to begin with, found satisfaction in her family, and the independence of her nature which went beyond the feminine ideal and found expression in a considerable amount of obstinacy, pugnacity and reserve. No appreciable hereditary taint, so my colleague told me, could be traced on either side of her family. It is true that her mother suffered for many years from a neurotic depression which had not been investigated; but her mother's brothers and sisters and her father and his family could be regarded as well-balanced people free from nervous trouble. No severe case of neuropsychosis [*Neuropsychose*] had occurred among her close relatives.

Such was the patient's nature, which was now assailed by painful emotions, beginning with the lowering effect of nursing her beloved father through a long illness.

There are good reasons for the fact that sick-nursing plays such a significant part in the prehistory of cases of hysteria. A number of the factors at work in this are obvious: the disturbance of one's physical health arising from interrupted sleep, the neglect of one's own person, the effect of constant worry on one's vegetative functions. But, in my view, the most important determinant is to be looked for elsewhere. Anyone whose mind is taken up by the hundred and one tasks of sick-nursing which follow one another in endless succession over a period of weeks and months will, on the one hand, adopt a habit of suppressing every
[162] sign of his own emotion and, on the other, will soon divert his attention away from his own impressions, since he has neither time nor strength to do justice to them. Thus he will accumulate a mass of impressions which are capable of affect, which are hardly sufficiently perceived and which, in any case, have not been weakened by abreaction. He is creating material for a 'retention hysteria'.[1] If the sick person recovers, all these impressions, of course, lose their significance. But if he dies, and the period of mourning sets in, during which the only things that seem to have value are those that relate to the person who has died, these impressions that have not yet been dealt with come into the picture as well; and after a short interval of exhaustion the hysteria, whose seeds were sown during the time of nursing, breaks out.

We also occasionally come across this same fact of the traumas accumulated during sick-nursing being dealt with subsequently [*nachträglichen*], where we get no general impression of illness but where the mechanism of hysteria is nevertheless retained. Thus I am acquainted with a highly gifted lady who suffers from slight nervous states and whose whole character bears evidence of hysteria, though she has never had to seek medical help or been unable to carry on her duties. She has already nursed to the end three or four of those whom she loved. Each time she reached a state of complete exhaustion; but she did not fall ill after these tragic efforts. Shortly after her patient's death, however, there would begin in her a work of reproduction which once more brought up before her eyes the scenes of the illness and death. Every day she would go through each impression once more, would weep over it and console herself – at her leisure, one might say. This process of dealing with her impressions was dovetailed into her everyday tasks without the two activities interfering with each other. The whole thing would pass through her mind in chronological sequence. I cannot say whether the work of recollection corresponded

1 [See p. 188 and *n*. 3 below.]

day by day with the past. I suspect that this depended on the amount of leisure which her current household duties allowed.[1]

In addition to these outbursts of weeping with which she made up arrears and which followed close upon the fatal termination of the [163] illness, this lady celebrated annual festivals of remembrance at the period of her various catastrophes, and on these occasions her vivid visual reproduction and expressions of feeling kept to the date precisely. For instance, on one occasion I found her in tears and asked her sympathetically what had happened that day. She brushed aside my question half-angrily: 'Oh no,' she said, 'it is only that the specialist was here again today and gave us to understand that there was no hope. I had no time to cry about it then.' She was referring to the last illness of her husband, who had died three years earlier. I should be very much interested to know whether the scenes which she celebrated at these annual festivals of remembrance were always the same ones or whether different details presented themselves for abreaction each time, as I suspect in view of my theory.[2] But I cannot discover with certainty. The lady,

1 [In this account of the 'work of recollection' Freud seems to be anticipating the 'work of mourning' which he described much later in his paper 'Mourning and Melancholia' (1916–17*g* [1915]), *RSE*, **14**, 218.]

2 I once learnt to my surprise that an 'abreaction of arrears' of this kind – though the impressions concerned were not derived from sick-nursing – can form the subject matter of an otherwise puzzling neurosis. This was so in the case of Fräulein Mathilde H., a good-looking, nineteen-year-old girl. When I first saw her she was suffering from a partial paralysis of the legs. Some months later, however, she came to me for treatment on account of a change in her character. She had become depressed to the point of a *taedium vitae*, utterly inconsiderate to her mother, irritable and inaccessible. The patient's picture as a whole forbade my assuming that this was a common melancholia. She was very easily put into a state of deep somnambulism, and I availed myself of this peculiarity of hers in order to give her commands and suggestions at every visit. She listened to these in deep sleep, to the accompaniment of floods of tears; but, apart from this, they caused very little change in her condition. One day she became talkative in her hypnosis and told me that the cause of her depression was the breaking off of her engagement, which had occurred several months earlier. Closer acquaintance with her fiancé had brought out more and more things that were unwelcome to her and her mother. On the other hand, the material advantages of the connection had been too obvious for it to be easy to decide to break it off. So for a long time they had both wavered and she herself had fallen into a state of indecision in which she regarded all that happened to her with apathy. In the end her mother uttered the decisive negative on her behalf. A little later she had woken up as though from a dream and begun to occupy her thoughts busily with the decision that had already been made and to weigh the pros and cons. This process, she told me, was still going on: she was living in the period of doubt, and every day she was possessed by the mood and thoughts which were appropriate to the day in the past with which she was occupied. Her irritability with her mother, too, had its basis only in the circumstances which prevailed at that time. In comparison with these activities of her thoughts, her present life seemed like a mere appearance of reality, like something in a dream. – I did not succeed in inducing the girl to talk again. I continued to address her while she was in deep somnambulism and saw her burst into tears each time without ever answering me; and one day, round about the anniversary of her engagement, her whole state of depression passed off – an event which brought me the credit of a great therapeutic success by hypnotism.

[164] who had no less strength of character than intelligence, was ashamed of the violent effect produced in her by these reminiscences.

I must emphasize once more: this woman is not ill; her postponed abreaction was not a hysterical process, however much it resembled one. We may ask why it should be that one instance of sick-nursing should be followed by a hysteria and another not. It cannot be a matter of individual predisposition, for this was present to an ample degree in the lady I have in mind.

But I must now return to Fräulein Elisabeth von R. While she was nursing her father, as we have seen, she for the first time developed a hysterical symptom – a pain in a particular area of her right thigh. It was possible by means of analysis to find an adequate elucidation of the mechanism of the symptom. It happened at a moment when the circle of ideas embracing her duties to her sick father came into conflict with the content of the erotic desire she was feeling at the time. Under the pressure of lively self-reproaches she decided in favour of the former, and in doing so brought about her hysterical pain.

According to the view suggested by the conversion theory of hysteria, what happened may be described as follows. She repressed her erotic idea from consciousness and transformed the amount of its affect into physical sensations of pain. It did not become clear whether she was presented with this first conflict on one occasion only or on several; the latter alternative is the more likely. A very similar conflict – though of higher ethical significance and even more clearly established by the analysis – developed once more some years later and led to an intensification of the same pains and to an extension beyond their original limits. Once again it was a circle of ideas of an erotic kind that came into conflict with all her moral ideas; for her inclinations centred upon her brother-in-law,
[165] and, both during her sister's lifetime and after her death, the thought of being attracted by precisely this man was totally unacceptable to her. The analysis provided detailed information about this conflict, which constituted the central point in the history of the illness. The germs of the patient's feeling for her brother-in-law may have been present for a long time; its development was favoured by physical exhaustion owing to more sick-nursing and by moral exhaustion owing to disappointments extending over many years. The coldness of her nature began to yield and she admitted to herself her need for a man's love. During the several weeks which she passed in his company at the health resort her erotic feelings as well as her pains reached their full height.

The analysis, moreover, gave evidence that during the same period the patient was in a special psychical state. The connection of this state with her erotic feelings and her pains seems to make it possible to understand what happened on the lines of the conversion theory. It is, I think, safe to say that at that time the patient did not become clearly conscious of her feelings for her brother-in-law, powerful though they were, except on a few occasions, and then only momentarily. If it had been otherwise, she would also inevitably have become conscious of the contradiction between those feelings and her moral ideas and would have experienced mental torments like those I saw her go through after our analysis. She had no recollection of any such sufferings; she had avoided them. It followed that her feelings themselves did not become clear to her. At that time, as well as during the analysis, her love for her brother-in-law was present in her consciousness like a foreign body, without having entered into relationship with the rest of her ideational life. With regard to these feelings she was in the peculiar situation of knowing and at the same time not knowing – a situation, that is, in which a psychical group was cut off. But this and nothing else is what we mean when we say that these feelings were not clear to her. We do not mean that their consciousness was of a lower quality or of a lesser degree, but that they were cut off from any free associative [*freien assoziativen*] connection of thought with the rest of the ideational content of her mind.

But how could it have come about that an ideational group with so much emotional emphasis on it was kept so isolated? In general, after all, the part played in association by an idea increases in proportion to the amount of its affect.

We can answer this question if we take into account two facts which [166]
we can make use of as being established with certainty. (1) Simultaneously with the formation of this separate psychical group the patient developed her hysterical pains. (2) The patient offered strong resistance to the attempt to bring about an association between the separate psychical group and the rest of the content of her consciousness; and when, in spite of this, the connection was accomplished she felt great psychical pain. Our view of hysteria brings these two facts into relation with the splitting of her consciousness by asserting that the second of them indicates the *motive* [*Motiv*] for the splitting of consciousness, while the first indicates its *mechanism*. The motive was that of defence [*Abwehr*], the refusal on the part of the patient's whole ego to come to terms with this ideational group. The mechanism was that of conversion: i.e. in place of the mental pains which she avoided, physical pains made their

appearance. In this way a transformation was effected which had the advantage that the patient escaped from an intolerable mental condition; though, it is true, this was at the cost of a psychical abnormality – the splitting of consciousness that came about – and of a physical illness – her pains, on which an astasia-abasia was built up.

I cannot, I must confess, give any hint of how a conversion of this kind is brought about. It is obviously not carried out in the same way as an intentional and voluntary action. It is a process which occurs under the pressure of the motive of defence in someone whose organization – or a temporary modification of it – has a proclivity in that direction.[1]

This theory calls for closer examination. We may ask: what *is* it that turns into physical pain here? A cautious reply would be: something that might have become, and should have become, *mental* pain. If we venture a little further and try to represent the ideational mechanism in a kind of algebraical picture, we may attribute a certain quota of affect to the ideational complex of these erotic feelings which remained unconscious, and say that this quantity (the quota of affect) is what was converted. It would follow directly from this description that the 'unconscious love' would have lost so much of its intensity through a conversion of this
[167] kind that it would have been reduced to no more than a weak idea. This reduction of strength would then have been the only thing which made possible the existence of these unconscious feelings as a separate psychical group. The present case, however, is not well fitted to give a clear picture of such a delicate matter. For in this case there was probably only partial conversion; in others it can be shown with likelihood that complete conversion also occurs, and that in it the incompatible idea has in fact been 'repressed', as only an idea of very slight intensity can be. The patients concerned declare, after associative connection with the incompatible idea has been established, that their thoughts had not been concerned with it since the appearance of the hysterical symptoms.

I have asserted [p. 147 above] that on certain occasions, though only for the moment, the patient recognized her love for her brother-in-law consciously. As an example of this we may recall the moment when she was standing by her sister's bed and the thought flashed through her mind: 'Now he is free and you can be his wife' [p. 139]. I must now consider the significance of these moments in their bearing on our view of the whole neurosis. It seems to me that the concept of a 'defence

1 [Cf. p. 107 f. above. The term 'somatic compliance' used in the 'Dora' case (*RSE*, **7**, 37–8) may perhaps refer to this proclivity.]

hysteria' in itself implies that at least *one* moment of this kind must have occurred. Consciousness, plainly, does not know in advance when an incompatible idea is going to crop up. The incompatible idea, which, together with its concomitants, is later excluded and forms a separate psychical group, must originally have been in communication with the main stream of thought. Otherwise the conflict which led to their exclusion could not have taken place.[1] It is these moments, then, that are to be described as 'traumatic': it is at these moments that conversion takes place, of which the results are the splitting of consciousness and the hysterical symptom. In the case of Fräulein Elisabeth von R. everything points to there having been several such moments – the scenes of the walk, the morning reverie, the bath, and at her sister's bedside. It is even possible that new moments of the same kind happened during the treatment. What makes it possible for there to be *several* of these traumatic moments is that an experience similar to the one which originally introduced the incompatible idea adds fresh excitation to the separated [168]
psychical group and so puts a temporary stop to the success of the conversion. The ego is obliged to attend to this sudden flare-up of the idea and to restore the former state of affairs by a further conversion. Fräulein Elisabeth, who was much in her brother-in-law's company, must have been particularly liable to the occurrence of fresh traumas. From the point of view of my present exposition, I should have preferred a case in which the traumatic history lay wholly in the past.

I must now turn to a point which I have described [p. 131 above] as offering a difficulty to the understanding of this case history. On the evidence of the analysis, I assumed that a first conversion took place while the patient was nursing her father, at the time when her duties as a nurse came into conflict with her erotic desires, and that what happened then was the prototype of the later events in the Alpine health resort which led to the outbreak of the illness. But it appeared from the patient's account that while she was nursing her father and during the time that followed – what I have described as the 'first period' – *she had no pains whatever and no locomotor weakness*. It is true that once during her father's illness she was laid up for a few days with pains in her legs, but it remained a question whether this attack was already to be ascribed to hysteria. No causal connection between these first pains and any psychical impression could be traced in the analysis. It is possible, and indeed probable, that what she was

1 It is otherwise in hypnoid hysteria, where the content of the separate psychical group would never have been in the ego consciousness. [Cf. p. 254 f. below.]

suffering from at that time were common rheumatic muscular pains. Moreover, even if we were inclined to suppose that this first attack of pains was the effect of a hysterical conversion as a result of the repudiation of her erotic thoughts at the time, the fact remains that the pains disappeared after only a few days, so that the patient had behaved differently in reality from what she seemed to indicate in the analysis. During her reproduction of what I have called the first period she accompanied all her stories about her father's illness and death, about her impressions of her dealings with her first brother-in-law, and so on, with manifestations of pain, whereas at the time of actually experiencing these impressions she had felt none. Is not this a contradiction which is calculated to reduce very considerably our belief in the explanatory value of an analysis such as this?

[169] I believe I can solve this contradiction by assuming that the pains – the products of conversion – did not occur while the patient was experiencing the impressions of the first period, but only after the event [*nachträglich*], that is, in the second period, while she was reproducing those impressions in her thoughts. That is to say, the conversion did not take place in connection with her impressions when they were fresh, but in connection with her memories of them. I even believe that such a course of events is nothing unusual in hysteria and indeed plays a regular part in the genesis of hysterical symptoms. But since an assertion like this is not self-evident, I will try to make it more plausible by bringing forward some other instances.

It once happened to me that a new hysterical symptom developed in a patient during the actual course of an analytic treatment of this kind so that I was able to set about getting rid of it on the day after its appearance. I will interpolate the main features of the case at this point. It was a fairly simple one, yet not without interest.

Fräulein Rosalia H., aged twenty-three, had for some years been undergoing training as a singer. She had a good voice, but she complained that in certain parts of its compass it was not under her control. She had a feeling of choking and constriction in her throat so that her voice sounded tight. For this reason her teacher had not yet been able to consent to her appearing as a singer in public. Although this imperfection affected only her middle register, it could not be attributed to a defect in the organ itself. At times the disturbance was completely absent and her teacher expressed great satisfaction; at other times, if she was in the least agitated, and sometimes without any apparent cause, the

constricted feeling would reappear and the production of her voice was impeded. It was not difficult to recognize a hysterical conversion in this very troublesome feeling. I did not take steps to discover whether there was in fact a contracture of some of the muscles of the vocal cords.[1] In the course of the hypnotic analysis which I carried out with the girl, I [170] learnt the following facts about her history and consequently about the cause of her trouble. She lost her parents early in life and was taken to live with an aunt who herself had numerous children. In consequence of this she became involved in a most unhappy family life. Her aunt's husband, who was a manifestly pathological person, brutally ill-treated his wife and children. He wounded their feelings more particularly by the way in which he showed an open sexual preference for the servants and nursemaids in the house; and the more the children grew up the more offensive this became. After her aunt's death Rosalia became the protector of the multitude of children who were now orphaned and oppressed by their father. She took her duties seriously and fought through all the conflicts into which her position led her, though it required a great effort to suppress the hatred and contempt which she felt for her uncle.[2] It was at this time that the feeling of constriction in her throat started. Every time she had to keep back a reply, or forced herself to remain quiet in the face of some outrageous accusation, she felt a scratching in her throat, a sense of constriction, a loss [*Versagen*][T] of voice – all the sensations localized in her larynx and pharynx which now interfered with her singing. It was not to be wondered at that she sought an opportunity of making herself independent and escaping the agitations and distressing experiences which were of daily occurrence in her uncle's house. A highly competent teacher of singing came to her assistance disinterestedly and assured her that her voice justified her in choosing the profession of singer. She now began to take lessons with him in secret. But she used often to hurry off to her singing lesson while she still had the constriction in her throat that used to be left over after

1 I had another case of a singer under my observation in which a contracture of the masseters made it impossible for her to practise her art. This young woman had been obliged to go on the stage by unfortunate events in her family. She was singing at a rehearsal in Rome at a time when she was in a state of great emotional excitement, and suddenly had a feeling that she could not close her open mouth and fell to the floor in a faint. The doctor who was called in brought her jaws together forcibly. But thenceforward the patient was unable to open her jaws by more than a finger's breadth and had to give up her new profession. When, several years later, she came to me for treatment, the causes of her emotional excitement had obviously long since disappeared, for some massage while she was in a state of light hypnosis sufficed to enable her mouth to open wide. Since then the lady has sung in public.

2 [*Footnote added* 1924:] In this instance, too [cf. p. 119 *n*. above], it was in fact the girl's father, not her uncle.

violent scenes at home. Consequently a connection was firmly established between her singing and her hysterical paraesthesia – a connection
[171] for which the way was prepared by the organic sensations set up by singing. The apparatus over which she ought to have had full control when she was singing turned out to be cathected with residues of innervations left over from the numerous scenes of suppressed emotion. Since then, she had left her uncle's house and had moved to another town in order to be away from her family. But this did not get over her difficulty.

This good-looking and unusually intelligent girl exhibited no other hysterical symptoms.

I did my best to get rid of this 'retention hysteria'[1] by getting her to reproduce all her agitating experiences and to abreact them after the event [*nachträgliches*]. I made her abuse her uncle, lecture him, tell him the unvarnished truth, and so on, and this treatment did her good. Unfortunately, however, she was living in Vienna under very unfavourable conditions. She had no luck with her relatives. She was being put up by another uncle, who treated her in a friendly way; but for that very reason her aunt took a dislike to her. This woman suspected that her husband had a deeper interest in his niece, and therefore chose to make her stay in Vienna as disagreeable as possible. The aunt herself in her youth had been obliged to give up a desire for an artistic career and envied her niece for being able to cultivate her talent, though in the girl's case it was not her desire but her need for independence that had determined her decision. Rosalie[2] felt so constrained in the house that she did not venture, for instance, to sing or play the piano while her aunt was within earshot and carefully avoided singing or playing to her uncle (who, incidentally, was an old man, her mother's brother) when there was a possibility of her aunt coming in. While I was trying to wipe out the traces of old agitations, new ones arose out of these relations with her host and hostess, which eventually interfered with the success of my treatment as well as bringing it to a premature end.

One day the patient came for her session with a new symptom, scarcely twenty-four hours old. She complained of a disagreeable pricking sensation in the tips of her fingers, which, she said, had been coming on every few hours since the day before and compelled her to make a
[172] peculiar kind of twitching movement with her fingers. I was not able to observe an attack; otherwise I should no doubt have been able to guess

1 [See below, p. 188 and *n.* 3.]

2 [The name is given this form at this point and below in all the German editions.]

from the nature of the movements what it was that had occasioned them. But I immediately tried to get on the track of the explanation of the symptom (it was in fact a minor hysterical attack) by hypnotic analysis. Since the whole thing had only been in existence such a short time I hoped that I should quickly be able to explain and get rid of the symptom. To my astonishment the patient produced a whole number of scenes, without hesitation and in chronological order, beginning with her early childhood.[1] They seemed to have in common her having had some injury done to her, against which she had not been able to defend herself, and which might have made her fingers jerk. They were such scenes, for instance, as of having had to hold out her hand at school and being struck on it with a ruler by her teacher. But they were quite ordinary occasions and I should have been prepared to deny that they could play a part in the aetiology of a hysterical symptom. But it was otherwise with one scene from her girlhood which followed. Her bad uncle, who was suffering from rheumatism, had asked her to massage his back and she did not dare to refuse. He was lying in bed at the time, and suddenly threw off the bedclothes, sprang up and tried to catch hold of her and throw her down. Massage, of course, was at an end, and a moment later she had escaped and locked herself in her room. She was clearly loath to remember this and was unwilling to say whether she had seen anything when he suddenly uncovered himself. The sensations in her fingers might be explained in this case by a suppressed impulse to punish him, or simply by her having been engaged in massaging him at the time. It was only after relating this scene that she came to the one of the day before, after which the sensations and jerking in her fingers had set in as a recurrent mnemic symbol. The uncle with whom she was now living had asked her to play him something. She sat down to the piano and accompanied herself in a song, thinking that her aunt had gone out; but suddenly she appeared in the door. Rosalie jumped up, slammed the lid of the piano and threw the music away. We can guess what the memory was that rose in her mind and what the train of thought was that she was fending off at that moment: it was a feeling of [173]
violent resentment at the unjust suspicion to which she was subjected and which should have made her leave the house, while in fact she was obliged to stay in Vienna on account of the treatment and had nowhere else where she could be put up. The movement of her fingers which I saw her make while she was reproducing this scene was one of twitching

1 [Apparently an exception to the general rule of inverse chronological order stated in footnote 1, p. 67 above.]

something away, in the way in which one literally and figuratively brushes something aside – tosses away a piece of paper or rejects a suggestion.

She was quite definite in her insistence that she had not noticed this symptom previously – that it had not been occasioned by the scenes she had first described. We could only suppose, therefore, that the event of the previous day had in the first instance aroused the memory of earlier events with a similar subject matter and that thereupon a mnemic symbol had been formed which applied to the whole group of memories. The energy for the conversion had been supplied, on the one hand, by freshly experienced affect and, on the other hand, by recollected affect.

When we consider the question more closely we must recognize that a process of this kind is the rule rather than the exception in the genesis of hysterical symptoms. Almost invariably when I have investigated the determinants of such conditions what I have come upon has not been a *single* traumatic cause but a group of similar ones. (This is well exemplified in the case of Frau Emmy – Case History 2.) In some of these instances it could be established that the symptom in question had already appeared for a short time after the first trauma and had then passed off, till it was brought on again and stabilized by a succeeding trauma. There is, however, in principle no difference between the symptom appearing in this temporary way after its first provoking cause and its being latent from the first. Indeed, in the great majority of instances we find that a first trauma has left no symptom behind, while a later trauma of the same kind produces a symptom, and yet that the latter could not have come into existence without the cooperation of the earlier provoking cause; nor can it be cleared up without taking all the provoking causes into account.

Stated in terms of the conversion theory, this incontrovertible fact of the
[174] summation of traumas and of the preliminary latency of symptoms tells us that conversion can result equally from fresh symptoms and from recollected ones. This hypothesis completely explains the apparent contradiction that we observed between the events of Fräulein Elisabeth von R.'s illness and her analysis. There is no doubt that the continued existence in consciousness of ideas whose affect has not been dealt with can be tolerated by healthy individuals up to a great amount. The view which I have just been putting forward does no more than bring the behaviour of hysterical people nearer to that of healthy ones. What we are concerned with is clearly a quantitative factor – the

question of how much affective tension of this kind an organism can tolerate. Even a hysteric can retain a certain amount of affect that has not been dealt with; if, owing to the occurrence of similar provoking causes, that amount is increased by summation to a point beyond the subject's tolerance, the impetus to conversion is given. Thus when we say that the construction of hysterical symptoms can proceed on the strength of recollected affects as well as fresh ones, we shall not be making any unfamiliar assertion, but stating something that is almost accepted as a postulate.

I have now discussed the motives and mechanism of this case of hysteria; it remains for me to consider how precisely the hysterical symptom was determined. Why was it that the patient's mental pain came to be represented by pains in the legs rather than elsewhere? The circumstances indicate that this somatic pain was not *created* by the neurosis but merely used, increased and maintained by it. I may add at once that I have found a similar state of things in almost all the instances of hysterical pains into which I have been able to obtain an insight. [Cf. above, pp. 84–5.] There had always been a genuine, organically founded pain present at the start. It is the commonest and most widespread human pains that seem to be most often chosen to play a part in hysteria: in particular, the periosteal and neuralgic pains accompanying dental disease, the headaches that arise from so many different sources and, not less often, the rheumatic muscular pains that are so often unrecognized [p. 63 *n*. 1 above]. In the same way I attribute an organic foundation to Fräulein Elisabeth von R.'s first attack of pain which occurred as far back as while she was nursing her father. I obtained no result when I tried to discover a psychical cause for it – and I am inclined, I must confess, to attribute a power of differential diagnosis to my method of [175]
evoking concealed memories, provided it is carefully handled. This pain, which was rheumatic in its origin,[1] then became a mnemic symbol of her painful psychical excitations; and this happened, so far as I can see, for more than one reason. The first and no doubt the most important of these reasons was that the pain was present in her consciousness at about the same time as the excitations. In the second place, it was connected, or could be connected, along a number of lines with the ideas in her mind at the time. The pain, indeed, may actually have been a consequence, though only a remote one, of the period of nursing – of the lack of exercise and reduced diet that her duties as a sick-nurse entailed. But the girl had no clear knowledge of this. More importance

1 It may, however, have been of a spinal-neurasthenic sort. [Cf. p. 131 *n*. above.]

should probably be attached to the fact that she must have felt the pain during that time at significant moments, for instance, when she sprang out of bed in the cold of winter in response to a call from her father [p. 130 f. above]. But what must have had a positively decisive influence on the direction taken by the conversion was another line of associative connection [p. 131 f.]: the fact that on a long succession of days one of her painful legs came into contact with her father's swollen leg while his bandages were being changed. The area on her right leg which was marked out by this contact remained thereafter the focus of her pains and the point from which they radiated. It formed an artificial hysterogenic zone whose origin could in the present case be clearly observed.

If anyone feels astonished at this associative connection between physical pain and psychical affect, on the ground of its being of such a multiple and artificial character, I should reply that this feeling is as little justified as astonishment at the fact that it is the rich people who own the most money.[1] Where there are no such numerous connections a hysterical symptom will not, in fact, be formed; for conversion will find no path open to it. And I can affirm that the example of Fräulein Elisabeth von R. was among the simpler ones as regards its determination. I have had the most tangled threads to unravel, especially in the case of Frau Cäcilie M.

[176] I have already discussed in the case history [p. 133 ff. above] the way in which the patient's astasia-abasia was built up on these pains, after a particular path had been opened up for the conversion. In that passage, however, I also expressed my view that the patient had created, or increased, her functional disorder by means of symbolization, that she had found in the astasia-abasia a somatic expression for her lack of an independent position and her inability to make any alteration in her circumstances, and that such phrases as 'not being able to take a single step forward', 'not having anything to lean upon', served as the bridge for this fresh act of conversion [p. 135].

I shall try to support this view by other examples. Conversion on the basis of simultaneity, where there is also an associative link, seems to make the smallest demands on hysterical disposition; conversion by symbolization, on the other hand, seems to call for the presence of a higher degree of hysterical modification. This could be observed in the case of Fräulein Elisabeth, but only in the later stage of her hysteria. The best examples of symbolization that I have seen occurred in Frau

1 [The allusion is to an epigram of Lessing's which Freud quotes again in *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 156.]

Cäcilie M., whose case I might describe as my most severe and instructive one. I have already explained [p. 62 *n*. above] that a detailed report of her illness is unfortunately impossible.

Frau Cäcilie suffered among other things from an extremely violent facial neuralgia which appeared suddenly two or three times a year, lasted for from five to ten days, resisted any kind of treatment and then ceased abruptly. It was limited to the second and third branches of one trigeminal, and since an abnormal excretion of urates was undoubtedly present and a not quite clearly defined 'acute rheumatism' played some part in the patient's history, a diagnosis of gouty neuralgia was plausible enough. This diagnosis was confirmed by the different consultants who were called in at each attack. Treatment of the usual kind was ordered: the electric brush, alkaline water, purges; but each time the neuralgia remained unaffected until it chose to give place to another symptom. Earlier in her life – the neuralgia was fifteen years old – her teeth were accused of being responsible for it. They were condemned to extraction, and one fine day, under narcosis, the sentence was carried out on seven of the criminals. This was not such an easy matter; her teeth were so firmly attached that the roots of most of them had to be left behind. This [177]
cruel operation had no result, either temporary or permanent. At that time the neuralgia raged for months on end. Even at the time of my treatment, at each attack of neuralgia the dentist was called in. On each occasion he diagnosed the presence of diseased roots and began to get to work on them; but as a rule he was soon interrupted. For the neuralgia would suddenly cease, and at the same time the demand for the dentist's services. During the interval her teeth did not ache at all. One day, when an attack was raging once more, the patient got me to give her hypnotic treatment. I laid a very energetic prohibition on her pains, and from that moment they ceased. I began at that time to harbour doubts of the genuineness of the neuralgia.

About a year after this successful hypnotic treatment Frau Cäcilie's illness took a new and surprising turn. She suddenly developed new pathological states, different from those that had characterized the last few years. But after some reflection the patient declared that she had had all of them before at various times during the course of her long illness, which had lasted for thirty years. There now developed a really surprising wealth of hysterical attacks which the patient was able to assign to their right place in her past. And soon, too, it was possible to follow the often highly involved trains of thought that determined the

order in which these attacks occurred. They were like a series of pictures with explanatory texts. Pitres must have had something of the sort in mind in putting forward his description of what he termed '*délire ecmnésique*'.[1] It was most remarkable to see the way in which a hysterical state of this kind belonging to the past was reproduced. There first came on, while the patient was in the best of health, a pathological mood with a particular colouring which she regularly misunderstood and attributed to some commonplace event of the last few hours. Then, to the accompaniment of an increasing clouding of consciousness, there followed hysterical symptoms: hallucinations, pains, spasms and long declamatory speeches. Finally, these were succeeded by the emergence in a hallucinatory form of an experience from the past which made it
[178] possible to explain her initial mood and what had determined the symptoms of her present attack. With this last piece of the attack her clarity of mind returned. Her troubles disappeared as though by magic and she felt well once again – till the next attack, half a day later. As a rule I was sent for at the climax of the attack, induced a state of hypnosis, called up the reproduction of the traumatic experience and hastened the end of the attack by artificial means. Since I assisted at several hundreds of such cycles with the patient, I gained the most instructive information on the way in which hysterical symptoms are determined. Indeed, it was the study of this remarkable case, jointly with Breuer, that led directly to the publication of our 'Preliminary Communication' [of 1893, which introduces the present volume].

In this phase of the work we came at last to the reproduction of her facial neuralgia, which I myself had treated when it appeared in contemporary attacks. I was curious to discover whether this, too, would turn out to have a psychical cause. When I began to call up the traumatic scene, the patient saw herself back in a period of great mental irritability towards her husband. She described a conversation which she had had with him and a remark of his which she had felt as a bitter insult. Suddenly she put her hand to her cheek, gave a loud cry of pain and said: 'It was like a slap in the face.' With this her pain and her attack were both at an end.

There is no doubt that what had happened had been a symbolization. She had felt as though she had actually been given a slap in the face. Everyone will immediately ask how it was that the sensation of a 'slap in the face' came to take on the outward forms of a trigeminal neuralgia,

1 ['*Ecmnesia*', according to Pitres (1891, **2**, 290), 'is a form of partial amnesia, in which the memory of events prior to a particular period in the patient's life is preserved in its entirety, whereas the memory of events subsequent to that period is completely abolished.']

why it was restricted to the second and third branches, and why it was made worse by opening the mouth and chewing – though, incidentally, not by talking.

Next day the neuralgia was back again. But this time it was cleared up by the reproduction of *another* scene, the content of which was once again a supposed insult. Things went on like this for nine days. It seemed to be the case that for years insults, and particularly spoken ones, had, through symbolization, brought on fresh attacks of her facial neuralgia.

But ultimately we were able to make our way back to her first attack of neuralgia, more than fifteen years earlier. Here there was no symbolization but a conversion through simultaneity. She saw a painful sight which was accompanied by feelings of self-reproach, and this led her to [179] force back another set of thoughts. Thus it was a case of conflict and defence. The generation of the neuralgia at that moment was only explicable on the assumption that she was suffering at the time from slight toothache or pains in the face, and this was not improbable, since she was just then in the early months of her first pregnancy.

Thus the explanation turned out to be that this neuralgia had come to be indicative of a particular psychical excitation by the usual method of conversion, but that afterwards it could be set going through associative reverberations from her mental life, or symbolic conversion. In fact, the same behaviour that we found in Fräulein Elisabeth von R.

I will give a second example which demonstrates the action of symbolization under other conditions. At a particular period, Frau Cäcilie was afflicted with a violent pain in her right heel – a shooting pain at every step she took, which made walking impossible. Analysis led us in connection with this to a time when the patient had been in a sanatorium abroad. She had spent a week in bed and was going to be taken down to the common dining room for the first time by the house physician. The pain came on at the moment when she took his arm to leave the room with him; it disappeared during the reproduction of the scene, when the patient told me she had been afraid at the time that she might not 'find herself on a right footing' with these strangers.

This seems at first to be a striking and even a comic example of the genesis of hysterical symptoms through symbolization by means of a verbal expression. Closer examination of the circumstances, however, favours another view of the case. The patient had been suffering at the time from pains in the feet generally, and it was on their account that she had been confined to bed so long. All that could be claimed on

behalf of symbolization was that the fear which overcame the patient, as she took her first steps, picked out from among all the pains that were troubling her at the time the one particular pain which was symbolically appropriate, the pain in her right heel, and developed it into a psychical pain and gave it special persistence.

In these examples the mechanism of symbolization seems to be reduced to secondary importance, as is no doubt the general rule. But I have examples at my disposal which seem to prove the genesis of hysterical symptoms through symbolization alone. The following is one of
[180] the best, and relates once more to Frau Cäcilie. When a girl of fifteen, she was lying in bed, under the watchful eye of her strict grandmother. The girl suddenly gave a cry; she had felt a penetrating pain in her forehead between her eyes, which lasted for weeks. During the analysis of this pain, which was reproduced after nearly thirty years, she told me that her grandmother had given her a look so 'piercing' that it had gone right into her brain. (She had been afraid that the old woman was viewing her with suspicion.) As she told me this thought she broke into a loud laugh, and the pain once more disappeared. In this instance I can detect nothing other than the mechanism of symbolization, which has its place, in some sense, midway between autosuggestion and conversion.

My observation of Frau Cäcilie M. gave me an opportunity of making a regular collection of symbolizations of this kind. A whole set of physical sensations which would ordinarily be regarded as organically determined were in her case of psychical origin or at least possessed a psychical meaning. A particular series of experiences of hers were accompanied by a stabbing sensation in the region of the heart (meaning 'it stabbed me to the heart'). The pain that occurs in hysteria of nails being driven into the head was without any doubt to be explained in her case as a pain related to thinking. ('Something's come into my head.') Pains of this kind were always cleared up as soon as the problems involved were cleared up. Running parallel to the sensation of a hysterical 'aura'[1] in the throat, when that feeling appeared after an insult, was the thought 'I shall have to swallow this'. She had a whole quantity of sensations and ideas running parallel with each other. Sometimes the sensation would call up the idea to explain it, sometimes the idea would create the sensation by means of symbolization, and not infrequently it had to be left an open question which of the two elements had been the primary one.

1 [See footnote 1, p. 111 above.]

I have not found such an extensive use of symbolization in any other patient. It is true that Frau Cäcilie M. was a woman who possessed quite unusual gifts, particularly artistic ones, and whose highly developed sense of form was revealed in some poems of great perfection. It is my opinion, however, that when a hysteric creates a somatic expression for an emotionally coloured idea by symbolization, this depends less than one would imagine on personal or voluntary factors. In taking a verbal [181] expression literally and in feeling the 'stab in the heart' or the 'slap in the face' after some slighting remark as a real event, the hysteric is not taking liberties with words, but is simply reviving once more the sensations to which the verbal expression owes its justification. How has it come about that we speak of someone who has been slighted as being 'stabbed to the heart' unless the slight had in fact been accompanied by a precordial sensation which could suitably be described in that phrase and unless it was identifiable by that sensation? What could be more probable than that the figure of speech 'swallowing something', which we use in talking of an insult to which no rejoinder has been made, did in fact originate from the innervatory sensations which arise in the pharynx when we refrain from speaking and prevent ourselves from reacting to the insult? All these sensations and innervations belong to the field of 'The Expression of the Emotions', which, as Darwin [1872] has taught us, consists of actions which originally had a meaning and served a purpose. These may now for the most part have become so much weakened that the expression of them in words seems to us only to be a figurative picture of them, whereas in all probability the description was once meant literally; and hysteria is right in restoring the original meaning of the words in depicting its unusually strong innervations. Indeed, it is perhaps wrong to say that hysteria creates these sensations by symbolization. It may be that it does not take linguistic usage as its model at all, but that both hysteria and linguistic usage alike draw their material from a common source.[1]

1 In states in which mental alteration goes deeper, we clearly also find a symbolic version in concrete images and sensations of more artificial turns of speech. Frau Cäcilie M. passed through a period during which she transformed every thought she had into a hallucination, the explanation of which often called for much ingenuity. She complained to me at that time of being troubled by a hallucination that her two doctors – Breuer and I – were hanging on two trees next to each other in the garden. The hallucination disappeared after the analysis had brought out the following explanation. The evening before, Breuer had refused to give her a drug she had asked for. She had then set her hopes on me but had found me equally hard-hearted. She was furious with us over this, and in her anger she thought to herself: 'There's nothing to choose between the two of them; one's the *pendant* [match] of the other.' – [A short summary of the case history of Fräulein Elisabeth was given by Freud in the second of his *Five Lectures* (1910*a*), *RSE*, **11**.]

Josef Breuer in 1897 (*aet*. 55)

*Josef Breuer in 1897 (*aet. *55)*

In his *Autobiographical Study*, Freud remembered Breuer like this: 'He was a man of striking intelligence and fourteen years older than myself. Our relations soon became more intimate and he became my friend and helper in my difficult circumstances. We grew accustomed to share all our scientific interests with each other. In this relationship the gain was naturally mine. The development of psychoanalysis afterwards cost me his friendship. It was not easy for me to pay such a price, but I could not escape it.' (*RSE*, **20**, 16.)

THEORETICAL
(BREUER)

III

THEORETICAL

(BREUER)

In the 'Preliminary Communication' which introduces this work we laid down the conclusions to which we were led by our observations, and I think that I can stand by them in the main. But the 'Preliminary Communication' is so short and concise that for the most part it was only possible in it to hint at our views. Now, therefore, that the case histories have brought forward evidence in support of our conclusions it may be permissible to state them at greater length. Even here, there is, of course, no question of dealing with the *whole* field of hysteria. But we may give a somewhat closer and clearer account (with some added reservations, no doubt) of those points for which insufficient evidence was adduced or which were not given enough prominence in the 'Preliminary Communication'. [185]

In what follows little mention will be made of the brain and none whatever of molecules. Psychical processes will be dealt with in the language of psychology; and, indeed, it cannot possibly be otherwise. If instead of 'idea' [*Vorstellung*] we chose to speak of 'excitation of the cortex' [*Rindenerregung*], the latter term would only have any meaning for us insofar as we recognized an old friend under that cloak and tacitly reinstated the 'idea'. For while ideas are constant objects of our experience and are familiar to us in all their shades of meaning, 'cortical excitations' are on the contrary rather in the nature of a postulate, objects which we hope to be able to identify in the future.[1] The substitution of one term for another would seem to be no more than a pointless disguise. Accordingly, I may perhaps be forgiven if I make almost exclusive use of psychological terms.

There is another point for which I must ask in advance for the reader's indulgence. When a science is making rapid advances, thoughts which

1 [Cf. our remarks in the Editors' Introduction to Freud's 'Project' (*RSE*, **1**, 317): given the almost total lack of scientific methods for determining physical correlates of mental processes in the 1890s, by remaining on psychological ground psychoanalysis was based on a sounder empirical footing than the physiology of the time could provide. See also Freud's (1891*b*) remarks concerning the relationship between 'ideas' and 'excitation of the cortex', which are strongly echoed by Breuer here.]

were first expressed by single individuals quickly become common property. Thus no-one who attempts to put forward today his views on
[186] hysteria and its psychical basis can avoid repeating a great quantity of other people's thoughts which are in the act of passing from personal into general possession. It is scarcely possible always to be certain who first gave them utterance, and there is always a danger of regarding as a product of one's own what has already been said by someone else. I hope, therefore, that I may be excused if few quotations are found in this discussion and if no strict distinction is made between what is my own and what originates elsewhere. Originality is claimed for very little of what will be found in the following pages.

(1) ARE ALL HYSTERICAL PHENOMENA IDEOGENIC?

In our 'Preliminary Communication' we discussed the psychical mechanism of 'hysterical phenomena', not of 'hysteria', because we did not wish to claim that this psychical mechanism or the psychical theory of hysterical symptoms in general has unlimited validity. We are not of the opinion that all the phenomena of hysteria come about in the manner described by us in that paper, nor do we believe that they are all ideogenic, that is, determined by ideas. In this we differ from Moebius, who in 1888 proposed to define as hysterical all pathological phenomena that are caused by ideas. This statement was later elucidated to the effect that only a part of the pathological phenomena correspond in their content to the ideas that cause them – those phenomena, namely, that are produced by allo- or autosuggestion, as, for instance, when the idea of not being able to move one's arm causes a paralysis of it; while another part of the hysterical phenomena, though caused by ideas, does not correspond to them in their content – as, for instance, when in one of our patients a paralysis of the arm was caused by the sight of snakelike objects [p. 36 above].

In giving this definition, Moebius is not merely proposing a modification in nomenclature and suggesting that in future we should only describe as hysterical those pathological phenomena which are ideogenic (determined by ideas); what he thinks is that all hysterical symptoms are ideogenic. 'Since ideas are very frequently the cause of hysterical phenomena, I believe that they always are.' He terms this an inference by analogy. I prefer to call it a generalization, the justification for which must first be tested.

Before any discussion of the subject, we must obviously decide what [187]
we understand by hysteria. I regard hysteria as a clinical picture which has been empirically discovered and is based on observation, in just the same way as tubercular pulmonary phthisis. Clinical pictures of this kind that have been arrived at empirically are made more precise, deeper and clearer by the progress of our knowledge; but they ought not to be and cannot be disrupted by it. Aetiological research has shown that the various constituent processes of pulmonary phthisis have various causes: the tubercle is due to *bacillus Kochii*, and the disintegration of tissue, the formation of cavities and the septic fever are due to other microbes.[1] In spite of this, tubercular phthisis remains a clinical unity and it would be wrong to break it up by attributing to it only the 'specifically tubercular' modifications of tissue caused by Koch's bacillus and by detaching the other modifications from it. In the same way hysteria must remain a clinical unity even if it turns out that its phenomena are determined by various causes, and that some of them are brought about by a psychical mechanism and others without it.

It is my conviction that this is in fact so; only a part of the phenomena of hysteria are ideogenic, and the definition put forward by Moebius tears in half the clinical unity of hysteria, and indeed the unity of one and the same symptom in the same patient.

We should be drawing an inference completely analogous to Moebius's 'inference by analogy' if we were to say that because ideas and perceptions very often give rise to erections we may assume that they alone ever do so and that peripheral stimuli set this vasomotor process in action only by a roundabout path through the psyche. We know that this inference would be false, yet it is based on at least as many facts as Moebius's assertion about hysteria. In conformity with our experience of a large number of physiological processes, such as the secretion of saliva or tears, changes in the action of the heart, etc., it is possible and plausible to assume that one and the same process may be set in motion equally by ideas and by peripheral and other non-psychical stimuli. The contrary would need to be proved and we are very far short of that. Indeed, it seems certain that many phenomena which are described as hysterical are not caused by ideas alone.

Let us consider an everyday instance. A woman may, whenever an [188]
affect arises, produce on her neck, breast and face an erythema appearing first in blotches and then becoming confluent. This is determined by ideas and therefore according to Moebius is a hysterical phenomenon.

1 [See Freud's (1883*a*) review of this topic, *NSW*, **1**.]

But this same erythema appears, though over a less extensive area, when the skin is irritated or touched, etc. This would *not* be hysterical. Thus a phenomenon which is undoubtedly a complete unity would on one occasion be hysterical and on another occasion not. It may of course be questioned whether this phenomenon, the erethism of the vasomotors, should be regarded as a specifically hysterical one or whether it should not be more properly looked upon simply as 'nervous'. But on Moebius's view the breaking up of the unity would necessarily result in any case and the affectively determined erythema would alone be called hysterical.

This applies in exactly the same way to the hysterical pains which are of so much practical importance. No doubt these are often determined directly by ideas. They are 'hallucinations of pain'. If we examine these rather more closely it appears that the fact of an idea being very vivid is not enough to produce them but that there must be a special abnormal condition of the apparatuses concerned with the conduction and sensation of pain, just as in the case of affective erythema an abnormal excitability of the vasomotors must be present. The phrase 'hallucinations of pain' undoubtedly gives the most pregnant description of the nature of these neuralgias, but it compels us, too, to carry over to them the views that we have formed on hallucinations in general. A detailed discussion of these views would not be in place here. I subscribe to the opinion that 'ideas', mnemic images pure and simple, without any excitation of the perceptual apparatus, never, even at their greatest vividness and intensity, attain the character of objective existence which is the mark of hallucinations.[1]

1 This perceptual apparatus, including the sensory areas of the cortex, must be different from the organ which stores up and reproduces sense impressions in the form of mnemic images. For the basic essential of the function of the perceptual apparatus is that its *status quo ante* should be capable of being restored with the greatest possible rapidity; otherwise no proper further perception could take place. The essential of memory, on the other hand, is that no such restoration should occur but that every perception should create changes that are permanent. It is impossible for one and the same organ to fulfil these two contradictory conditions. The mirror of a reflecting telescope cannot at the same time be a photographic plate. I am in agreement with Meynert, in the sense of believing, as I have said, that what gives hallucinations their objective character is an excitation of the perceptual apparatus (though I do not agree with him when he speaks of an excitation of the subcortical centres). If the perceptual organ is excited by a mnemic image, we must suppose that that organ's excitability has been changed in an abnormal direction, and that this change is what makes hallucination possible. [The thesis that a single apparatus could not perform the functions both of perception and memory was adopted by Freud in Chapter VII of his *Interpretation of Dreams* (1900*a*), *RSE*, **5**, 480 f. He had already accepted it in his posthumous 'Project' (1950*a*, Part I, Section 3), written a few months after the publication of the present work, as well as in a letter to Fliess of December 6, 1896, and he returned to it in Chapter IV of *Beyond the Pleasure Principle* (1920*g*), ibid., **18**, 24 f., and in his paper on the 'Mystic Writing-Pad' (1925*a*), ibid., **19**, 228. In the last but one of these he explicitly attributes this line of thought to Breuer.]

This applies to sensory hallucinations and still more to hallucinations [189]
of pain. For it does not seem possible for a healthy person to endow the memory of a physical pain with even the degree of vividness, the distant approximation to the real sensation, which can, after all, be attained by optical and acoustic mnemic images. Even in the normal hallucinatory state of healthy people which occurs in sleep there are never, I believe, dreams of pain unless a real sensation of pain is present. This 'retrogressive' excitation,[1] emanating from the organ of memory and acting on the perceptual apparatus by means of ideas, is therefore in the normal course of things still more difficult in the case of pain than in that of visual or auditory sensations. Since hallucinations of pain arise so easily in hysteria, we must posit an abnormal excitability of the apparatus concerned with sensations of pain.

This excitability makes its appearance not only under the spur of ideas but of peripheral stimuli in just the same way as the erethism of the vasomotors which we discussed above.

It is a matter of daily observation to find that in people with normal nerves peripheral pains are brought on by pathological processes, not in themselves painful, in other organs. Thus headaches arise from relatively [190]
insignificant changes in the nose or neighbouring cavities,[2] and again, neuralgias of the intercostal and brachial nerves from the heart, etc. If the abnormal excitability, which we have been obliged to postulate as a necessary condition of hallucinations of pain, is present in a patient, that excitability is also at the disposal, so to speak, of the irradiations that I have just mentioned. The irradiations that occur also in non-neurotic people are made more intense, and irradiations are formed of a sort which, it is true, we only find in neurotic patients but which are based on the same mechanism as the others. Thus, ovarian neuralgia depends, I believe, on states of the genital apparatus. That its causes are psychical would have to be proved, and this is not achieved by showing that that particular kind of pain, like any other, can be produced under hypnosis as a hallucination, or that its causes *can* be psychical. Like erythema or one of the normal secretions, it arises both from psychical and from purely somatic causes. Are we to describe only the first kind as hysterical – cases which we know have a psychical origin? If so, the commonly

1 [This idea of the retrogressive nature of hallucination, already alluded to above (p. 168 *n.* 1), was adopted by Freud in his discussion of dreams in the posthumous 'Project' (see Appendix A, *RSE*, **1**, 369 ff.). It can also be found in Chapter VII of *The Interpretation of Dreams* (1900*a*), ibid., **5**, 484 ff., where the term 'regression' is used.]

2 [An allusion to Fliess's theory.]

observed cases of ovarian neuralgia would have to be excluded from the hysterical syndrome, and this will hardly do.

If a slight injury to a joint is gradually followed by a severe arthralgia, no doubt the process involves a psychical element, viz. a concentration of attention on the injured part, which intensifies the excitability of the nerve tracts concerned. But this can hardly be expressed by saying that the hyperalgesia has been caused by ideas.

The same is true of the pathological *diminution* of sensation. It is quite unproved and improbable that general analgesia or analgesia of individual parts of the body unaccompanied by anaesthesia is caused by ideas. And even if the discoveries of Binet and Janet were to be fully confirmed to the effect that hemianaesthesia is determined by a peculiar psychical condition, by a splitting of the psyche, the phenomenon would be a psychogenic but not an ideogenic one, and therefore, according to Moebius, should not be termed hysterical.

If, therefore, there are a large number of characteristic hysterical phenomena which we cannot suppose to be ideogenic, it would seem right to limit the application of Moebius's thesis. We shall not define as hysterical those pathological phenomena which are caused by ideas, but
[191] assert only that a great number of hysterical phenomena, probably more than we suspect today, are ideogenic. But the fundamental pathological change which is present in every case and enables ideas as well as non-psychological stimuli to produce pathological effects lies in an abnormal excitability of the nervous system.[1] How far this excitability is itself of psychical origin is another question.

Yet even though only some of the phenomena of hysteria are ideogenic, nevertheless it is precisely they that may be described as the specifically hysterical ones, and it is the investigation of them, the discovery of their psychical origin, which constitutes the most important recent step forward in the theory of the disorder. The further question then arises: how do these phenomena come about? What is their 'psychical mechanism'?

This question requires a quite different answer in the case of each of the two groups into which Moebius divides ideogenic symptoms [p. 166 above]. Those pathological phenomena which correspond in their content to the instigating idea are relatively understandable and clear. If the idea of a heard voice does not merely cause it to echo faintly

1 Attributed by Oppenheim [1890] to 'instability of the molecules'. It may be possible at a later stage to replace the very vague statement in the text above by a more precise and significant formula. [Cf. below, p. 214 ff.]

in the 'inward ear', as it does in healthy people, but causes it to be perceived in a hallucinatory manner as a real, objective acoustic sensation, this may be equated with familiar phenomena of normal life – with dreams – and is quite intelligible on the hypothesis of abnormal excitability. We know that with every voluntary movement it is the idea of the result to be achieved which initiates the relevant muscular contraction; and it is not very hard to see that the idea that this contraction is impossible will impede the movement (as happens in paralysis by suggestion).

The situation is otherwise with those phenomena which have no logical connection with the determining idea. (Here, too, normal life offers parallels, as, for instance, blushing for shame.) How do they arise? Why does an idea in a sick man evoke one particular entirely irrational movement or hallucination which does not in any way correspond to it?

In our 'Preliminary Communication' we felt able to say something [192] about this causal relation on the basis of our observations. In our exposition of the subject, however, we introduced and employed without apology the concept of 'excitations which flow away or have to be abreacted'.[1] This concept is of fundamental importance for our theme and for the theory of the neuroses in general, and it seems to demand and to deserve a more detailed examination. Before I proceed to this, I must ask to be forgiven for taking the reader back to the basic problems of the nervous system. A feeling of oppression is bound to accompany any such descent to the 'Mothers' [i.e. exploration of the depths].[2]

But any attempt at getting at the roots of a phenomenon inevitably leads in this way to basic problems which cannot be evaded. I hope therefore that the abstruseness of the following discussion may be viewed with indulgence.

(2) INTRACEREBRAL TONIC EXCITATION – AFFECTS

(A)

We know two extreme conditions of the central nervous system: a clear waking state and dreamless sleep. A transition between these is afforded by conditions of every degree of decreasing clarity. What interests us here is not the question of the purpose of sleep and its physical basis (its

1 [This is not an actual quotation from the 'Preliminary Communication', where this underlying hypothesis is nowhere explicitly mentioned. Cf. the remarks on this in the Editors' Introduction, p. xx f. above.]

2 [An allusion to Faust's mysterious researches (in Goethe's *Faust*, Part II, Act I).]

chemical or vasomotor determinants) but the question of the essential distinction between the two conditions.

We can give no direct information about the deepest, dreamless sleep, or the very reason that all observations and experiences are excluded by the state of total unconsciousness. But as regards the neighbouring condition of sleep accompanied by dreams, the following assertions can be made. In the first place, when in that condition we intend to make voluntary movements – of walking, speaking, etc. – this does not result in the corresponding contractions of the muscles being voluntarily initiated, as
[193] they are in waking life. In the second place, sensory stimuli are perhaps perceived (for they often make their way into dreams) but they are not apperceived, i.e. do not become conscious perceptions. Again, ideas that emerge do not, as in waking life, activate all the ideas which are connected with them and which are present in potential consciousness; a great number of the latter remain unexcited. (For instance, we find ourselves talking to a dead person without remembering that he is dead.) Furthermore, incompatible ideas can be present simultaneously without mutually inhibiting each other, as they do in waking life. Thus, association is defective and incomplete. We may safely assume that in the deepest sleep this severance of connections between the psychical elements is carried still further and becomes total.

On the other hand, when we are fully awake every act of will initiates the corresponding movement; sense impressions become conscious perceptions; and ideas are associated with the whole store present in potential consciousness. In that condition the brain functions as a unit with complete internal connections.

We shall perhaps only be describing these facts in other words if we say that in sleep the paths of connection and conduction in the brain are not traversable by excitations of the psychical elements (? cortical cells), whereas in waking life they are completely so traversable.

The existence of these two different conditions of the paths of conduction can, it seems, only be made intelligible if we suppose that in waking life those paths are in a state of tonic excitation (what Exner [1894, 93] calls 'intercellular tetanus'[1]), that this intracerebral tonic excitation is what determines their conductive capability, and that the diminution and disappearance of that excitation is what sets up the state of sleep.

We ought not to think of a cerebral path of conduction as resembling a telephone wire which is only excited electrically at the moment at

1 ['Tetanus' in physiology refers to the prolonged contraction of a muscle caused by rapidly repeated stimuli.]

which it has to function (that is, in the present context, when it has to transmit a signal). We ought to liken it to a telephone line through which there is a constant flow of galvanic current and which can no longer be excited if that current ceases. Or better, let us imagine a widely ramified electrical system for lighting and the transmission of motor power; what is expected of this system is that simple establishment of a contact shall be able to set any lamp or machine in operation. To make this possible, [194] so that everything shall be ready to work, there must be a certain tension present throughout the entire network of lines of conduction, and the dynamo engine must expend a given quantity of energy for this purpose. In just the same way there is a certain amount of excitation present in the conductive paths of the brain when it is at rest but awake and prepared to work.[1]

This view of the matter is supported by the fact that merely being awake, without doing any work, gives rise to fatigue and produces a need for sleep. The state of waking in itself causes a consumption of energy.

Let us imagine a man in a state of intense expectation, which is not, however, directed to any particular sensory field. We then have before us a brain which is quiescent but prepared for action. We may rightly sup- [195] pose that in such a brain all the paths of conduction are at the maximum of their conductive capability – that they are in a state of tonic excitation. It is a significant fact that in ordinary language we speak of such a state as one of tension. Experience teaches us what a strain this state is and how fatiguing, though no actual motor or psychical work is performed in it.

1 I may perhaps venture here to indicate briefly the notion on which the above statements are based. We usually think of the sensory nerve cells as being passive receptive organs. This is a mistake. For the mere existence of a system of associative fibres proves that these sensory nerve cells also send out excitation into the nerve fibres. If excitation from two sensory cells flows into a nerve fibre that connects them – whether *per continuitatem* or *per contiguitatem* [i.e. whether it is an extension of them or is in contact with them] – then a state of tension must exist in it. This state of tension has the same relation to the excitation flowing away in, for instance, a peripheral motor fibre as hydrostatic pressure has to the living force of flowing water or as electric tension has to an electric current. If all the nerve cells are in a state of mean excitation and are exciting their nerve processes [axons], the whole immense network forms a single reservoir of 'nervous tension'. Apart then from a potential energy which lies quiescent in the chemical substance of the cell and an unknown form of kinetic energy which is discharged when the fibres are in a state of excitation, we must assume the existence of yet another quiescent state of nervous excitation: tonic excitation or nervous tension. [This footnote and the corresponding passage in the text above seem to have been regarded by Freud as his ground for attributing to Breuer the distinction between the 'free' and 'bound' forms of psychical energy and the allied distinction between the primary and secondary systems of psychical functioning. In his paper on 'The Unconscious' (1915*e*), *RSE*, **14**, 165, and in *Beyond the Pleasure Principle* (1920*g*), ibid., **18**, 26, he definitely asserts that these ideas are derived from Breuer's contribution to *Studies on Hysteria*, but he gives no more precise reference. Freud had already adopted the idea in Chapter VII of *The Interpretation of Dreams* (1900*a*), ibid., **5**, 536 ff.; but the question is discussed at greater length towards the end of the first section of Part III of the posthumously published 'Project' (1950*a*). See Appendix C, ibid., **1**, 417 ff. The terms 'free' and 'bound' energy are attributable to Helmholtz.]

This is an exceptional state, which, precisely on account of the great consumption of energy involved, cannot be tolerated for long. But even the normal state of being wide awake calls for an amount of intracerebral excitation varying between limits that are not very widely separated. Every diminishing degree of wakefulness down to drowsiness and true sleep is accompanied by correspondingly lower degrees of excitation.

When the brain is performing actual work, a greater consumption of energy is no doubt required than when it is merely *prepared* to perform work. (In just the same way the electrical system described above by way of comparison must cause a greater amount of electrical energy to flow into the conducting lines when a large number of lamps or motors are switched into the circuit.) Where functioning is normal no more energy is liberated than is immediately employed in activity. The brain, however, behaves like one of those electrical systems of restricted capability which are unable to produce both a large amount of light and of mechanical work at the same time. If it is transmitting power, only a little energy is available for lighting, and *vice versa*. Thus we find that if we are making great muscular efforts we are unable to engage in continuous thought, or that if we concentrate our attention in one sensory field the efficiency of the other cerebral organs is reduced – that is to say, we find that the brain works with a varying but limited amount of energy.

The non-uniform distribution of energy is no doubt determined by what Exner [1894, 165] calls 'facilitation by attention' – by an increase in the conductive capability of the paths in use and a decrease in that of the others; and thus in a working brain the 'intracerebral tonic excitation', too, is non-uniformly distributed.[1]

[196] We wake up a person who is sleeping – that is, we suddenly raise the quantity of his tonic intracerebral excitation – by bringing a lively sensory stimulus to bear upon him. Whether alterations in the blood circulation in the brain are essential links here in the causal chain, and whether the blood vessels are directly dilated by the stimulus, or whether the dilatation is a consequence of the excitation of the cerebral elements – all this is undecided. What is certain is that the state of excitation, entering through a gateway of the senses, spreads over the brain from that point,

1 The conception [*Auffassung*] of the energy of the central nervous system as being a quantity distributed over the brain in a changing and fluctuating manner is an old one. 'La sensibilité', wrote Cabanis [1824, **3**, 153], 'semble se comporter à la manière d'un fluide dont la quantité totale est déterminée et qui, toutes les fois qu'il se jette en plus grande abondance dans un de ses canaux, diminue proportionellement dans les autres.' (Quoted from Janet, 1894, 277.) ['Sensibility seems to behave like a fluid whose total quantity is fixed and which, whenever it pours into one of its channels in greater abundance, becomes proportionally less in the others.']

becomes diffused and brings all the paths of conduction into a state of higher facilitation.

It is still not in the least clear, of course, how *spontaneous* awakening occurs – whether it is always one and the same portion of the brain that is the first to enter a state of waking excitation and the excitation then spreads from there, or whether sometimes one and sometimes another group of elements acts as the awakener. Nevertheless, spontaneous awakening, which, as we know, can take place in complete quiet and darkness without any external stimulus, proves that the development of energy is based on the vital process of the cerebral elements themselves. A muscle remains unstimulated, quiescent, however long it has been in a state of rest and even though it has accumulated a maximum of tensile force. This is not so with the cerebral elements. We are no doubt right in supposing that during sleep the latter regain their previous condition and gather tensile force. When this has happened to a certain degree, when, as we may say, a certain level has been reached, the surplus flows away into the paths of conduction, facilitates them and sets up the intracerebral excitation of the waking state.

We can find an instructive example of the same thing in waking life. When the waking brain has been quiescent for a considerable time without transforming tensile force into live energy by functioning, there arises a need and an urge for activity. Long motor quiescence creates a need for movement (compare the aimless running round of a caged animal) and if [197]
this need cannot be satisfied a distressing feeling sets in. Lack of sensory stimuli, darkness and complete silence become a torture; mental repose, lack of perceptions, ideas and associative activity produce the torment of boredom. These unpleasurable feelings [*Unlustgefühle*][T] correspond to *Unlust*
an 'excitement', to an increase in normal intracerebral excitation.

Thus the cerebral elements, after being completely restored, liberate a certain amount of energy even when they are at rest; and if this energy is not employed functionally it increases the normal intracerebral excitation. The result is a feeling of unpleasure. Such feelings are always generated when one of the organism's needs fails to find satisfaction. Since these feelings disappear when the surplus quantity of energy which has been liberated is employed functionally, we may conclude that the removal of such surplus excitation is a need of the organism. And here for the first time we meet the fact that there exists in the organism a '*tendency to keep intracerebral excitation constant*' (Freud).[1]

1 [This seems to be the first explicit enunciation of Freud's 'principle of constancy'. It had been used previously by him in writings that were only posthumously published (1941*a* [1892] and 1940*d* [1892]). Freud developed the subject further in another posthumously published work, his

Such a surplus of intracerebral excitation is a burden and a nuisance, and an urge to use it up arises in consequence. If it cannot be used in sensory or ideational activity, the surplus flows away in purposeless motor action, in walking up and down, and so on, and this we shall meet with later as the commonest method of discharging excessive tensions.

We are familiar with the great individual variations which are found in this respect: the great differences between lively people and inert and lethargic ones, between those who 'cannot sit still' and those who have an 'innate gift for lounging on sofas' and between mentally agile minds and dull ones which can tolerate intellectual rest for an unlimited length
[198] of time. These differences, which make up a man's 'natural temperament', are certainly based on profound differences in his nervous system – on the degree to which the functionally quiescent cerebral elements liberate energy.

We have spoken of a tendency on the part of the organism to keep tonic cerebral excitation constant. A tendency of this kind is, however, only intelligible if we can see what need it fulfils. We can understand the tendency in warm-blooded animals to keep a constant mean temperature, because our experience has taught us that that temperature is an optimum for the functioning of their organs. And we make a similar assumption in regard to the constancy of the water content of the blood; and so on. I think that we may also assume that there is an optimum for the height of the intracerebral tonic excitation. At that level of tonic excitation the brain is accessible to all external stimuli, the reflexes are facilitated, though only to the extent of normal reflex activity, and the store of ideas is capable of being aroused and open to association in the mutual relation between individual ideas which corresponds to a clear and reasonable state of mind. It is in this state that the organism is best prepared for work.

The situation is already altered by the uniform [pp. 173–4 above] heightening of tonic excitation which constitutes 'expectation'. This makes the organism hyperaesthetic towards sensory stimuli, which quickly become distressing, and also increases its reflex excitability above what is useful (proneness to fright). No doubt this state is useful for some situations and purposes; but if it appears spontaneously and not for any such reasons, it does not improve our efficiency but impairs

'Project' (1950*a*), which was written a few months after the publication of the present *Studies*, and in which he names the hypothesis 'the principle of neuronal inertia'. (See, in particular, Section 1 of Part I of that work.) He had, however, stated its essence in the lecture (1893*h*) which he delivered at about the time of publication of the 'Preliminary Communication'. The subject is discussed more fully in the Editors' Introduction, p. xx f. above.]

it. In ordinary life we call this being 'nervous'. In the great majority of forms of increase in excitation, however, the overexcitation is *not* uniform, and this is always detrimental to efficiency. We call this 'excitement'. That the organism should tend to maintain the optimum of excitation and to return to that optimum after it has been exceeded is not surprising, but quite in keeping with other regulating factors in the organism.

I shall venture once more to return to my comparison with an electrical lighting system. The tension in the network of lines of conduction in such a system has an optimum too. If this is exceeded its functioning may easily be impaired; for instance, the electric light filaments may be quickly burnt through. I shall speak later of the damage done to the [199]
system itself through a breakdown of its insulation or through 'short-circuiting'.

(B)

Our speech, the outcome of the experience of many generations, distinguishes with admirable delicacy between those forms and degrees of heightening of excitation which are still useful for mental activity [i.e. in spite of rising above the optimum (see last paragraph but one)] because they raise the free energy of all cerebral functions uniformly, and those forms and degrees which restrict that activity because they partly increase and partly inhibit these psychical functions in a manner that is *not* uniform. The first are given the name of 'incitement', and the second 'excitement'.[1] An interesting conversation, or a cup of tea or coffee has an 'inciting' [stimulating] effect; a dispute or a considerable dose of alcohol has an 'exciting' one. While incitement only arouses the urge to employ the increased excitation functionally, excitement seeks to discharge itself in more or less violent ways which are almost or even actually pathological. Excitement constitutes the psychophysical basis of the affects,[2] and these will be discussed below. But I must first touch briefly on some physiological and endogenous causes of increases of excitation.

Among these, in the first place, are the organism's major physiological needs and drives [*Triebe*][T]: need for oxygen, craving for food, and thirst. Since the excitement which they set going is linked to certain sensations and purposive ideas, it is not such a pure example of increase of excitation as the one discussed above [pp. 174–5], which arose solely

1 [In German '*Anregung*' = 'incitement', 'stimulation'; '*Aufregung*' = 'excitement', 'agitation'.]

2 [Misprinted as 'effects' in *SE*.]

from the quiescence of the cerebral elements. The former always has its special colouring. But it is unmistakable in the anxious agitation which accompanies dyspnoea and in the restlessness of a starving man.

The increase of excitation that comes from these sources is determined by the chemical change in the cerebral elements themselves, which are short of oxygen, of tensile force or of water. It flows away along preformed motor paths, which lead to the satisfaction of the need that set it going: dyspnoea leads to breathing with effort, and hunger and thirst to a search for and attainment of food and water. The
[200] principle of the constancy of excitation scarcely comes into operation as far as this kind of excitement is concerned; for the interests which are served by the increase in excitation in these cases are of far greater importance to the organism than the re-establishment of normal conditions of functioning in the brain. It is true that we see animals in a zoo running backwards and forwards excitedly before feeding time; but this may no doubt be regarded as a residue of the preformed motor activity of looking for food, which has now become useless owing to their being in captivity, and not as a means of freeing the nervous system of excitement.

If the chemical structure of the nervous system has been permanently altered by a persistent introduction of foreign substances, then a lack of these substances will cause states of excitement, just as the lack of normal nutritive substances does in healthy people. We see this in the excitement occurring in abstinence from narcotics.

A transition between these endogenous increases of excitation and the psychical affects in the narrower sense is provided by sexual excitation and sexual affect. Sexuality at puberty appears in the first of these forms, as a vague, indeterminate, purposeless heightening of excitation. As development proceeds, this endogenous heightening of excitation, determined by the functioning of the sex glands, becomes firmly linked (in the normal course of things) with the perception or idea of the other sex – and, indeed, with the idea of a particular individual, where the remarkable phenomenon of falling in love occurs. This idea takes over the whole quantity of excitation liberated by the sexual drive. It becomes an 'affective idea'; that is to say, when it is actively present in consciousness it sets going the accretion of excitation which in point of fact originated from another source, namely the sex glands.

The sexual drive is undoubtedly the most powerful source of persisting accretions of excitation (and consequently of neuroses). Such increases are distributed very unevenly over the nervous system. When they reach a considerable degree of intensity the train of ideas becomes disturbed and the relative value of the ideas is changed; and in orgasm[1] thought is almost completely extinguished.

Perception too – the psychical interpretation of sense impressions – is [201]
impaired. An animal which is normally timid and cautious becomes blind and deaf to danger. On the other hand, at least in males, there is an intensification of the aggressive instinct [*Instinkt*][T]. Peaceable animals become dangerous until their excitation has been discharged in the motor activities of the sexual act.

(c)

A disturbance like this of the dynamic equilibrium of the nervous system – a non-uniform distribution of increased excitation – is what makes up the psychical side of affects.

No attempt will be made here to formulate either a psychology or a physiology of the affects. I shall only discuss a single point, which is of importance for pathology, and moreover only for ideogenic affects – those which are called up by perceptions and ideas. (Lange, 1885, [62 ff.], has rightly pointed out that affects can be caused by toxic substances, or, as psychiatry teaches us, above all by pathological changes, almost in the same way as they can by ideas.)

It may be taken as self-evident that all the disturbances of mental equilibrium which we call acute affects go along with an increase of excitation. (In the case of *chronic* affects, such as sorrow and care, that is to say protracted anxiety, the complication is present of a state of severe fatigue which, though it maintains the non-uniform distribution of excitation, nevertheless reduces its height.) But this increased excitation cannot be employed in psychical activity. All powerful affects restrict association – the train of ideas. People become 'senseless' with anger or fright. Only the group of ideas which provoked the affect persists in consciousness, and it does so with extreme intensity. Thus the excitement cannot be levelled out by associative activity.

Affects that are 'active' or 'sthenic' do, however, level out the increased excitation by *motor* discharge. Shouting and jumping for joy, the

1 ['*Orgasmus*' in the first and second German editions. In later editions this is misprinted '*Organismus*'.]

increased muscular tone of anger, angry words and retaliatory deeds – all these allow the excitation to flow away in movements. Mental pain discharges it in difficult breathing and in an act of secretion: in sobs and tears. It is a matter of everyday experience that such reactions reduce excitement and allay it. As we have already remarked [p. 7 above],
[202] ordinary language expresses this in such phrases as 'to cry oneself out', 'to blow off steam', etc. What is being got rid of is nothing else than the increased cerebral excitation.

Only some of these reactions, such as angry deeds and words, serve a purpose in the sense of making any change in the actual state of affairs. The rest serve no purpose whatever, or rather their only purpose is to level out the increase of excitation and to establish psychical equilibrium. Insofar as they achieve this they serve the 'tendency to keep [intra]cerebral excitation constant' [p. 175 above].

The 'asthenic' affects of fright and anxiety do not bring about this reactive discharge. Fright paralyses outright the power of movement as well as of association, and so does anxiety if the single useful reaction of running away is excluded by the cause of the affect of anxiety or by circumstances. The excitation of fright disappears only by a gradual levelling out.

Anger has adequate reactions corresponding to its cause. If these are not feasible, or if they are inhibited, they are replaced by substitutes. Even angry words are substitutes of this kind. But other, even quite purposeless, acts may appear as substitutes. When Bismarck had to suppress his angry feelings in the king's presence, he relieved himself afterwards by smashing a valuable vase on the floor. This deliberate replacement of one motor act by another corresponds exactly to the replacement of natural pain reflexes by other muscular contractions. When a tooth is extracted the preformed reflex is to push away the dentist and utter a cry; if, instead of that, we contract the muscles of our arms and press against the sides of the chair, we are shifting the quantum of excitation that has been generated by the pain from one group of muscles to another. [Cf. p. 81 above.] In the case of violent spontaneous toothache, where there is no preformed reflex apart from groaning, the excitation flows off in aimless pacing up and down. In the same way we transpose the excitation of anger from the adequate reaction to another one, and we feel relieved provided it is used up by *any* strong motor innervation.

abführen If, however, the affect can find no discharge [*Abfuhr*]^{T} of excitation of any kind along these lines, then the situation is the same with anger as with fright and anxiety. The intracerebral excitation is powerfully

increased, but is employed neither in associative nor in motor activity. In normal people the disturbance is gradually levelled out. But in some, [203] abnormal reactions appear. An 'abnormal expression of the emotions', as Oppenheim [1890] says, is formed.[1]

(3) HYSTERICAL CONVERSION

I shall scarcely be suspected of identifying nervous excitation with electricity, if I return once more to the comparison with an electrical system. If the tension in such a system becomes excessively high, there is danger of a break occurring at weak points in the insulation. Electrical phenomena then appear at abnormal points; or, if two wires lie close beside each other, there is a short-circuit. Since a permanent change has been produced at these points, the disturbance thus brought about may constantly recur if the tension is sufficiently increased. An abnormal 'facilitation' has taken place.

That the conditions applying in the nervous system are to some extent similar can well be maintained. It forms throughout an interconnected whole; but at many points in it great, though not insurmountable, resistances are interposed, which prevent the general, uniform distribution of excitation. Thus in normal people in a waking state excitation in the organ of ideation does not pass over to the organs of perception: such people do not hallucinate [cf. p. 169 above]. In the interests of the safety and efficiency of the organism, the nervous apparatuses of the complexes of organs which are of vital importance – the circulatory and digestive organs – are separated by strong resistances from the organs of ideation. Their independence is assured. They are not affected directly by ideas. But the resistances which prevent the passage of intracerebral excitation to the circulatory and digestive apparatuses vary in strength from one individual to another. All degrees of affective excitability are to be found between, on the one hand, the ideal (which is rarely met with today) of a man who is absolutely free from 'nerves', whose heart action remains constant in every situation and is only affected by the particular work it has to perform, the man who has a good appetite and digestion, whatever danger he is in – between a man of this kind and, on the other hand, a 'nervous' man who has palpitations and diarrhoea on the smallest provocation.

However this may be, there are resistances in normal people against [204] the passage of cerebral excitation to the vegetative organs. These

1 [This formulation does not appear in Oppenheim (1890) – only 'abnormal excitability'.]

resistances correspond to the insulation of electrical conducting lines. At points at which they are abnormally weak they are broken through when the tension of cerebral excitation is high, and this – the affective excitation – passes over to the peripheral organs. There ensues an 'abnormal expression of emotion'.

Of the two factors which we have mentioned as being responsible for this result, one has already been discussed by us in detail. This first factor is a high degree of intracerebral excitation which has failed to be levelled down either by ideational activities or by motor discharge, or which is too great to be dealt with in this way.

The second factor is an abnormal weakness of the resistances in particular paths of conduction. This may be determined by the individual's initial constitution (innate disposition); or it may be determined by states of excitation of long duration which, as one might say, loosen the whole structure of his nervous system and lower all its resistances (pubertal disposition); or it may be determined by weakening influences, such as illness and undernourishment (disposition due to states of exhaustion). The resistance of particular paths of conduction may be lowered by a previous illness of the organ concerned, which has facilitated the paths to and from the brain. A diseased heart is more susceptible to the influence of an affect than is a healthy one. 'I have a sounding-board in my abdomen,' I was told by a woman who suffered from parametritis, 'if anything happens, it starts up my old pain.' (Disposition through local illness.)

The motor actions in which the excitation of affects is normally discharged are ordered and coordinated even though they are often useless. But an excessively strong excitation may bypass or break through the coordinative centres and flow off in primitive movements. In infants, apart from the respiratory action of screaming, affects only produce and find expression in uncoordinated contractions of the muscles of this primitive kind – in arching the body and kicking about. As development proceeds, the musculature passes more and more under the control of the power of coordination and the will. But the opisthotonus, which represents the maximum of motor effort of the total somatic musculature, and the clonic movements of kicking and threshing about, persist throughout life as the form of reaction for the maximal excitation of the brain – for the purely physical excitation in epileptic attacks as well as for the discharge of maximal affects in the shape of more or less epileptoid convulsions (viz. the purely motor part of hysterical attacks).

[205]

It is true that abnormal affective reactions of this kind are characteristic of hysteria. But they also occur apart from that illness. What they indicate is a more or less high degree of nervous disorder, not hysteria. Such phenomena cannot be described as hysterical if they appear as consequences of an affect which, though of great intensity, has an objective basis, but only if they appear with apparent spontaneity as manifestations of an illness. These latter, as many observations, including our own, have shown, are based on recollections which revive the original affect – or rather, *which would revive it if those reactions did not, in fact, occur instead*.

It may be taken for granted that a stream of ideas and recollections runs through the consciousness of any reasonably intelligent person while his mind is at rest. These ideas are so unvivid that they leave no trace behind in the memory and it is impossible afterwards to say how the associations occurred. If, however, an idea comes up that originally had a strong affect attached to it, that affect is revived with more or less intensity. The idea which is thus 'coloured' by affect emerges in consciousness clearly and vividly. The strength of the affect which can be released by a memory is very variable, according to the amount to which it has been exposed to 'wearing away' by different influences, and especially according to the degree to which the original affect has been 'abreacted'. We pointed out in our 'Preliminary Communication' [p. 7 f. above] to what a varying extent the affect of anger at an insult, for instance, is called up by a recollection, according to whether the insult has been repaid or endured in silence. If the psychical reflex was fully achieved on the original occasion, the recollection of it releases a far smaller quantity of excitation.[1] If not, the recollection is perpetually [206]
forcing on to the subject's lips the abusive words which were originally suppressed and which would have been the psychical reflex to the original stimulus.

1 The drive to revenge, which is so powerful in natural man and is disguised rather than repressed by civilization, is nothing whatever but the excitation of a reflex that has not been released. To defend oneself against injury in a fight and, in doing so, to injure one's opponent is the adequate and preformed psychical reflex. If it has been carried out insufficiently or not at all, it is constantly released again by recollection, and the 'drive to revenge' comes into being as an irrational volitional impulse, just as do all other 'drives'. The proof of this lies precisely in the irrationality of the impulse, its divorce from any question of usefulness or expediency, indeed in its disregard of all considerations of the subject's own safety. As soon as the reflex has been released, the irrational nature of the impulse can become conscious.

Ein andres Antlitz, eh sie geschehen,
Ein anderes zeigt die vollbrachte Tat.

[Literally: 'A deed shows one countenance before it has happened and another after it has been accomplished.' Schiller, *Die Braut von Messina*, III, 5.]

If the original affect was discharged not in a normal but in an 'abnormal' reflex, this latter is equally released by recollection. The excitation arising from the affective idea is 'converted' (Freud)[1] into a somatic phenomenon.

Should this abnormal reflex become completely facilitated by frequent repetition, it may, it seems, drain away the operative force of the releasing ideas so totally that the affect itself emerges to a minimal extent only, or not at all. In such a case the 'hysterical conversion' is complete. The idea, moreover, which now no longer produces any psychical consequences, may be overlooked by the subject, or may be promptly forgotten if it emerges, like any other idea which is unaccompanied by affect.

It may be easier to accept the possibility of a cerebral excitation which should have given rise to an idea being replaced in this way by an excitation of some peripheral path, if we call to mind the inverse course of events which follows when a preformed reflex fails to occur. I will select an extremely trivial example – the sneezing reflex. If a stimulus of the mucous membrane of the nose fails for any reason to release this pre-
[207] formed reflex, a feeling of excitation and tension arises, as we all know. The excitation, which has been unable to flow off along motor paths, now, inhibiting all other activity, spreads over the brain. This everyday example gives us the pattern of what happens when a psychical reflex, even the most complicated one, fails to occur. The excitement which we have discussed above [p. 183 *n.*] as characteristic of the drive to revenge is in essentials the same. And we can follow the same process even up to the highest regions of human achievement. Goethe did not feel he had dealt with an experience till he had discharged it in creative artistic activity. This was in his case the preformed reflex belonging to affects, and so long as it had not been carried out the distressing increase in his excitation persisted.

Intracerebral excitation and the excitatory process in peripheral paths are of reciprocal magnitudes: the former increases if and so long as no reflex is released; it diminishes and disappears when it has been transformed into peripheral nervous excitation. Thus it seems understandable that no observable affect is generated if the idea that should have given rise to it immediately releases an abnormal reflex into which the

1 [Freud comments, near the beginning of his 'History of the Psychoanalytic Movement' (1914*d*), *RSE*, **14**, 6–7, on the appearance here of his name in brackets. He remarks that Breuer seemed to be implying that the priority for this piece of theory belonged to Freud. 'I believe', he goes on, 'that actually this distinction relates only to the name, and that the conception came to us simultaneously and together.' The first published text in which the term 'conversion' appeared was nevertheless Freud's (1894*a*), ibid., **3**, 46.]

excitation flows away as soon as it is generated. The 'hysterical conversion' is then complete. The original intracerebral excitation belonging to the affect has been transformed into the excitatory process in the peripheral paths. What was originally an affective idea now no longer provokes the affect but only the abnormal reflex.[1]

We have now gone a step beyond the 'abnormal expression of the emotions'. Hysterical phenomena (abnormal reflexes) do not seem to be ideogenic even to intelligent patients who are good observers, because the idea that gave rise to them is no longer coloured with affect and no longer marked out among other ideas and memories. They emerge as [208]
purely somatic phenomena, apparently without psychical roots.

What is it that determines the discharge of affect in such a way that one particular abnormal reflex is produced rather than some other? Our observations answer this question in many instances by showing that here again the discharge follows the 'principle of least resistance' and takes place along those paths whose resistances have already been weakened by concurrent circumstances. This covers the case which we have already mentioned [p. 182 above] of a particular reflex being facilitated by already existing somatic illness. If, for instance, someone suffers often from cardiac pains, these will also be provoked by affects. Alternatively, a reflex may be facilitated by the fact that the muscular innervation concerned was deliberately intended at the moment at which the affect originally occurred. Thus, Anna O. (in our first case history) [p. 35 above] tried, in her fright, to stretch out her right arm that had gone to sleep owing to pressure against the back of the chair, in order to ward off the snake; and from that time on the tetanus in her right arm was provoked by the sight of any snakelike object. Or again [p. 36], in her emotion, she brought her eyes forcibly together in order to read the hands of the watch, and thereupon a convergent squint became one of the reflexes of that affect. And so on.

This is due to the operation of simultaneity, which, indeed, governs our normal associations.[2] Every sense perception calls back into consciousness any other sense perception that appeared originally at the

1 I am anxious not to drive the analogy with an electrical system to death. In view of the totally dissimilar conditions it can scarcely illustrate the processes in the nervous system, and can certainly not explain them. But I may once more recall the case in which, owing to excessively high tension, the insulation of the wires in a lighting system breaks down and a 'short-circuit' occurs at some point in it. If electrical phenomena (such as overheating or sparking) occur at this point, the lamp to which the wire leads fails to light. In just the same way, the affect fails to appear if the excitation flows away in an abnormal reflex and is converted into a somatic phenomenon.

2 [Cf. the 'Project' (Freud, 1950*a*), *RSE*, **1**, 343 and 363 *n*. 6.]

same time. (Cf. the textbook example of the visual image of a sheep and the sound of its bleating, etc.) If the original affect was accompanied by a vivid sense impression, the latter is called up once more when the affect is repeated; and since it is a question of discharging excessively great excitation, the sense impression emerges, not as a recollection, but as a hallucination. Almost all our case histories provide instances of this. It is also what happened in the case of a woman who experienced a painful affect at a time when she was having violent toothache due to periostitis, and who thenceforward suffered from infra-orbital neuralgia whenever the affect was renewed or even recollected [pp. 157–9 above].

[209] What we have here is the facilitation of abnormal reflexes according to the general laws of association. But sometimes (though, it must be admitted, only in higher degrees of hysteria) true sequences of associated ideas lie between the affect and its reflex. Here we have *determination through symbolism*.[1] What unites the affect and its reflex is often some ridiculous play upon words or associations by sound, but this only happens in dreamlike states when the critical powers are low and lies outside the group of phenomena with which we are here dealing.

In a large number of cases the path taken by the train of determination remains unintelligible to us, because we often have a very incomplete insight into the patient's mental state and an imperfect knowledge of the ideas which were active at the time of the origin of the hysterical phenomenon. But we may assume that the process is not entirely unlike what we can observe clearly in more favourable cases.

The experiences which released the original affect, the excitation of which was then converted into a somatic phenomenon, are described by us as *psychical traumas*, and the pathological manifestation arising in this way, as *hysterical symptoms of traumatic origin*. (The term 'traumatic hysteria' has already been applied to phenomena which, as being consequences of physical injuries – traumas in the narrowest sense of the word – form part of the class of 'traumatic neuroses'.)

The genesis of hysterical phenomena that are determined by traumas finds a perfect analogy in the hysterical conversion of the psychical excitation which originates, not from external stimuli nor from the inhibition of normal psychical reflexes, but from the inhibition of the course of association. The simplest example and model of this is afforded by the excitation which arises when we cannot recollect a name or cannot solve a riddle, and so on. If someone tells us the name or gives us the answer to the riddle, the chain of associations is ended, and the excitation vanishes,

1 [Cf. the 'Project' (Freud, 1950*a*), *RSE*, **1**, 374 and *n*. 1.]

just as it does on the ending of a reflex chain. The strength of the excitation caused by the blocking of a line of associations is in direct ratio to the interest which we take in them – that is, to the degree to which they set our will in motion. Since, however, the search for a solution to the problem, or whatever it may be, always involves a large amount of work, though it may be to no purpose, even a powerful excitation finds employment and does not press for discharge, and consequently never becomes pathogenic.

It does, however, become pathogenic if the course of associations is [210] inhibited owing to ideas of equal importance being irreconcilable – if, for instance, fresh thoughts come into conflict with old-established ideational complexes. Such are the torments of religious doubt to which many people succumb and many more succumbed in the past. Even in such cases, however, the excitation and the accompanying psychical pain (the feeling of unpleasure) only reach any considerable height if some volitional interest of the subject's comes into play – if, for instance, a doubter feels himself threatened in the matter of his happiness or his salvation. Such a factor is always present, however, when the conflict is one between firmly rooted complexes of moral ideas in which one has been brought up and the recollection of actions or merely thoughts of one's own which are irreconcilable with them; when, in other words, one feels the pangs of conscience. The volitional interest in being pleased with one's own personality and satisfied with it comes into operation here and increases to the highest degree the excitation due to the inhibition of associations. It is a matter of everyday experience that a conflict like this between irreconcilable ideas has a pathogenic effect. What are mostly in question are ideas and processes connected with sexual life: masturbation in an adolescent with moral sensibilities; or, in a strictly conscientious married woman, becoming aware of an attraction to a man who is not her husband. Indeed, the first emergence of sexual feelings and ideas is very often in itself enough to bring about an intense state of excitation, owing to its conflicting with a deeply rooted idea of moral purity.[1]

A state of excitation of this kind is usually followed by psychical consequences, such as pathological depression and anxiety states (Freud [1895*b*]). Sometimes, however, concurrent circumstances bring about an abnormal somatic phenomenon in which the excitation is discharged. Thus there may be vomiting when the feeling of uncleanness produces a physical feeling of nausea, or a *tussis nervosa*, as in Anna O. (Case

1 Cf. on this point some interesting observations and comments by Benedikt [1894, 51 ff.].

History 1 [p. 40 above]), when moral anxiety provokes a spasm of the glottis, and so on.[1]

[211] There is a normal, appropriate reaction to excitation caused by very vivid and irreconcilable ideas – namely, to communicate them by speech. An amusingly exaggerated picture of the urge to do this is given in the story of Midas's barber, who spoke his secret aloud to the reeds.[2] We meet the same urge as one of the basic factors of a major historical institution – the Roman Catholic confessional. Telling things is a relief; it discharges tension even when the person to whom they are told is not a priest and even when no absolution follows. If the excitation is denied this outlet it is sometimes converted into a somatic phenomenon, just as is the excitation belonging to traumatic affects. The whole group of hysterical phenomena that originate in this way may be described, with Freud, as *hysterical phenomena of retention*.[3]

The account that we have hitherto given of the mechanism by which hysterical phenomena originate is open to the criticism that it is too schematic and simplifies the facts. In order that a healthy person who is not initially neuropathic may develop a genuine hysterical symptom, with its apparent independence of the mind and with a somatic existence in its own right, there must always be a number of concurrent circumstances.

The following case will serve as an example of the complicated nature of the process. A twelve-year-old boy, who had previously suffered from *pavor nocturnus* and whose father was highly neurotic, came home from school one day feeling unwell. He complained of difficulty in swallowing
[212] and headache. The family doctor assumed that the cause was a sore throat. But the condition did not improve even after several days. The

1 Compare a passage in Mach's 'Bewegungsempfindungen' [1875] which deserves to be recalled in this connection: 'It has often been found during the experiments (on giddiness) which I have described, that in general a feeling of nausea set in if it was difficult to bring the sensations of movement into harmony with the optical impressions. It appeared as though a part of the stimulus proceeding from the labyrinth had been compelled to leave the optic tracts, which were closed to it on account of another stimulus, and to enter upon quite other tracts. . . . I have also repeatedly observed a feeling of nausea in making an attempt to combine stereoscopic images which are widely separated.'

Here we have nothing less than the physiological pattern for the generation of pathological, hysterical phenomena as a result of the coexistence of vivid ideas which are irreconcilable with one another.

2 [Viz.: 'King Midas has ass's ears.']

3 [The first publication in which Freud used the term 'retention hysteria' was his first paper on 'The Neuropsychoses of Defence' (1894*a*, Section I). It was briefly mentioned on pp. 144 and 152 above, and is discussed at greater length below on pp. 254–5, where Freud appears to attribute the term jointly to Breuer and himself, and where, incidentally, he throws doubts on the importance of the concept.]

boy refused food and vomited when it was pressed on him. He moved about listlessly, without energy or enjoyment; he wanted to lie in bed all the time and was very much run down physically. When I saw him five weeks later, he gave the impression of being a shy and shut-in child, and I became convinced that his condition had a psychical basis. On being questioned closely, he brought up a trivial explanation – a severe reproof given by his father – which had clearly not been the real cause of his illness. Nor could anything be learnt from his school. I promised that I would extract the information later under hypnosis. This, however, turned out to be unnecessary. In response to strong appeals from his clever and energetic mother, he burst into tears and told the following story. While he was on his way home from school he had gone into a urinal, and a man had held out his penis to him and asked him to take it into his mouth. He had run away in terror, and nothing else had happened to him. But he was ill from that instant. As soon as he had made his confession he recovered completely. – In order to produce the anorexia, the difficulty in swallowing and the vomiting, several factors were required: the boy's innate neurotic nature, his severe fright, the irruption of sexuality in its crudest form into his childish temperament and, as the specifically determining factor, the idea of disgust. The illness owed its persistence to the boy's silence, which prevented the excitation from finding its normal outlet.

In all other cases, as in this one, there must be a convergence of several factors before a hysterical symptom can be generated in anyone who has hitherto been normal. Such symptoms are invariably 'overdetermined', to use Freud's expression.[1]

It may be assumed that an overdetermination of this sort is also present when the same affect has been called out by a series of several provoking causes. The patient and those about him attribute the hysterical symptom only to the last cause, though that cause has as a rule merely brought to light something that had already been almost accomplished by other traumas. [213]

A girl of seventeen[2] had her first hysterical attack (which was followed by a number of others) when a cat jumped on her shoulder in the dark.

1 [This seems to be the first published appearance of the term '*überdeterminiert*'[T], which is used by Freud himself below on p. 234. On p. 258 he uses the synonymous German word '*überbestimmt*', and this already occurs in his monograph on aphasia (1891*b*) in a passage on learning to speak which can be found translated in an Appendix to the paper on 'The Unconscious' (1915*e*), *RSE*, **14**, 187 f. It is, it must be added, unlikely that the notion of multiple causation should never have been expressed earlier by other writers in similar terminology.]

2 I have to thank Herr Assistent Dr Paul Karplus for this case.

The attack seemed simply to be the result of fright. Closer investigation showed, however, that the girl, who was particularly good-looking and was not properly looked after, had recently had a number of more or less brutal attempts made on her, and had herself been sexually excited by them. (Here we have the factor of disposition.) A few days before, a young man had attacked her on the same dark staircase and she had escaped from him with difficulty. This was the actual psychical trauma, which the cat did no more than make manifest. But it is to be feared that in many such cases the cat is regarded as the *causa efficiens*.

In order for the repetition of an affect to bring about a conversion in this way, it is not always necessary that there should be a number of *external* provoking causes; the renewal of the affect in *memory* is often also enough, if the recollection is repeated rapidly and frequently, immediately after the trauma and before its affect has become weakened. This is enough if the affect was a very powerful one. Such is the case in traumatic hysteria, in the narrower sense of the word. During the days following a railway accident, for instance, the subject will live through his frightful experiences again both in sleeping and waking, and always with the renewed affect of fright, till at last, after this period of 'psychical working out [*élaboration*]' (in Charcot's phrase [cf. p. 118 above]) or of 'incubation', conversion into a somatic phenomenon takes place. (Though there is another factor concerned which we shall have to discuss later.)

As a rule, however, an affective idea is promptly subjected to 'wearing away', to all the influences touched on in our 'Preliminary Communication' (p. 8 above), which deprive it little by little of its quota
[214] of affect.[1] Its revival causes an ever-diminishing amount of excitation, and the recollection thus loses the capacity to contribute to the production of a somatic phenomenon. The facilitation of the abnormal reflex disappears and the *status quo ante* is thereupon re-established.

The 'wearing-away' influences, however, are all of them effects of association, of thinking, of corrections by reference to other ideas. This process of correction becomes impossible if the affective idea is withdrawn from 'associative contact'. When this happens the idea retains its whole quota of affect. Since at every renewal the whole sum of excitation of the original affect is liberated once more, the facilitation of the

1 ['*Affektwert*' (here and a few lines lower down), literally 'affective value'. This is an approximate synonym for '*Affektbetrag*', as is shown by a sentence in Freud's paper in French on organic and hysterical paralyses (1893*c*). He there uses the words '*valeur affective*' and adds in parentheses the German '*Affektbetrag*'. This latter term is regularly translated here as 'quota of affect', e.g. on p. 148 above.]

abnormal reflex that was started at the time is finally completed; or, if the facilitation was already complete, it is maintained and stabilized. The phenomenon of hysterical conversion is in this way permanently established.

Our observations show two ways in which affective ideas can be excluded from association.

The first is 'defence' [*Abwehr*][T],[1] the deliberate suppression of distressing ideas which seem to the subject to threaten his happiness or his self-esteem. In his [first] paper on 'The Neuropsychoses of Defence' (1894*a*) and in his case histories in the present volume, Freud has discussed this process, which undoubtedly possesses very high pathological significance. We cannot, it is true, understand how an idea can be deliberately repressed [*verdrängt*][T] from consciousness. But we are perfectly familiar with the corresponding positive process, that of concentrating attention on an idea, and we are just as unable to say how we effect *that*. Ideas, then, from which consciousness is diverted, which are not thought about, are also withdrawn from the wearing-away process and retain their quota of affect undiminished. *Verdrängung*

We have further found that there is another kind of idea that remains exempt from being worn away by thought. This may happen, not because one does not *want* to remember the idea, but because one *cannot* remember it: because it originally emerged and was endowed with affect in states in respect of which there is amnesia in waking consciousness – that is, in hypnosis or in states similar to it. The latter seem to be of the highest importance for the theory of hysteria, and accordingly deserve a somewhat fuller examination.[2]

(4) HYPNOID STATES

When, in our 'Preliminary Communication' [p. 11 above], we put forward the thesis that the basis and *sine qua non* of hysteria is the existence of hypnoid states, we were overlooking the fact that Moebius had already said exactly the same thing in 1890. 'The necessary condition for the (pathogenic) operation of ideas is, on the one hand, an [215]

1 [See footnote, p. 9 above.]

2 When, here and later on, we speak of ideas that are currently present and operative but yet unconscious, we are seldom concerned with *single* ideas (such as the big snake hallucinated by Anna O. which started her contracture). It is almost always a question of *complexes* of ideas, of recollections of external events and trains of thought of the subject's own. It may sometimes happen that every one of the individual ideas comprised in such a complex of ideas is thought of consciously, and that what is exiled from consciousness is only the particular combination of them.

innate – that is, hysterical – disposition and, on the other, a special frame of mind. We can only form an imprecise idea of this frame of mind. It must resemble a state of hypnosis; it must correspond to some kind of vacancy of consciousness in which an emerging idea meets with no resistance from any other – in which, so to speak, the field is clear for the first comer. We know that a state of this kind can be brought about not only by hypnotism but by emotional shock (fright, anger, etc.) and by exhausting factors (sleeplessness, hunger, and so on).' [Moebius, 1894*a*, 17.]

The problem to whose solution Moebius was here making a tentative approach is that of the generating of somatic phenomena by ideas. He here recalls the ease with which this can occur under hypnosis, and regards the operation of affects as analogous. Our own, somewhat different, view on the operation of the affects has been fully explained above [p. 179 ff.]. I need not, therefore, enter further into the difficulty involved in Moebius's assumption that in anger there is a 'vacancy of consciousness'[1] (which admittedly exists in fright and prolonged anxiety) or into the more general difficulty of drawing an analogy between the state of excitation in an affect and the quiescent state in hypnosis. We shall come back later [p. 196 below], however, to these remarks by Moebius, which in my opinion embody an important truth.

[216] For us, the importance of these states which resemble hypnosis – 'hypnoid' states – lies, in addition and most especially, in the amnesia that accompanies them and in their power to bring about the *splitting of the mind* which we shall discuss presently and which is of fundamental significance for 'major hysteria'. We still attribute this importance to hypnoid states. But I must add a substantial qualification to our thesis. Conversion – the ideogenic production of somatic phenomena – can also come about apart from hypnoid states. Freud has found in the deliberate amnesia of defence a second source, independent of hypnoid states, for the construction of ideational complexes which are excluded from associative contact. But, accepting this qualification, I am still of the opinion that hypnoid states are the cause and necessary condition of many, indeed of most, major and complex hysterias.

First and foremost, of course, among hypnoid states are to be numbered true autohypnoses, which are distinguished from artificial hypnoses only by the fact of their originating spontaneously. We find them in a number of fully developed hysterias, occurring with varying

1 It is possible that by this description Moebius means nothing else than the inhibition [*Hemmung*][T] of the current of ideas – an inhibition which certainly occurs in the case of affects, though owing to entirely different causes from those operating in hypnosis.

frequency and duration, and often alternating rapidly with normal waking states (cf. Case Histories 1 and 2). On account of the dreamlike nature of their content, they often deserve the name of '*delirium hystericum*'. What happens during autohypnotic states is subject to more or less total amnesia in waking life (whereas it is completely remembered in artificial hypnosis). The amnesia withdraws the psychical products of these states, the associations that have been formed in them, from any correction during waking thought; and since in autohypnosis criticism and supervision by reference to other ideas is diminished, and, as a rule, disappears almost completely, the wildest delusions may arise from it and remain untouched for long periods. Thus it is almost only in these states that there arises a somewhat complicated irrational "'symbolic" relation between the precipitating cause and the pathological phenomenon' [p. 5 above], which, indeed, is often based on the most absurd similarities of sound and verbal associations. The absence of criticism in autohypnotic states is the reason why autosuggestions so frequently arise from them – as, for instance, when a paralysis remains behind after a hysterical attack. But, and this may be merely by chance, we have scarcely ever in our analyses come across an instance of a hysterical phenomenon originating in this manner. We have always found it happen, in autohypnosis no less than outside it, as a result of the same process – namely, conversion of an affective excitation. [217]

In any case, this 'hysterical conversion' takes place more easily in autohypnosis than in the waking state, just as suggested ideas are realized physically as hallucinations and movements so much more easily in artificial hypnosis. Nevertheless, the process of conversion of excitation is essentially the same as has been described above. When once it has taken place, the somatic phenomenon is repeated if the affect and the autohypnosis occur simultaneously. And in that case it seems as though the hypnotic state has been called up by the affect itself. Accordingly, so long as there is a clear-cut alternation between hypnosis and full waking life, the hysterical symptom remains restricted to the hypnotic state and is strengthened there by repetition; moreover, the idea that gave rise to it is exempt from correction by waking thoughts and their criticism, precisely because it never emerges in clear waking life.

Thus with Anna O. (Case History 1) the contracture of her right arm, which was associated in her autohypnosis with the affect of anxiety[1] and the idea of the snake, remained for four months restricted to the moments during which she was in a hypnotic state (or, if we consider this term

1 [*Angsteffekte* ('effect of anxiety') in the German original – clearly an error.]

inappropriate for *absences* of very short duration, a hypnoid one), though it recurred frequently. The same thing happened with other conversions that were carried out in her hypnoid state; and in this way the great complex of hysterical phenomena grew up in a condition of complete latency and came into the open when her hypnoid state became permanent. [Cf. p. 38 f. above.]

The phenomena which have arisen in this way emerge into clear consciousness only when the split in the mind, which I shall discuss later, has been completed, and when the alternation between waking and hypnoid states has been replaced by a coexistence between the normal and the hypnoid complexes of ideas.

Are hypnoid states of this kind in existence before the patient falls ill, and how do they come about? I can say very little about this, for apart from the case of Anna O. we have no observations at our disposal which might throw light on the point. It seems certain that with her the
[218] autohypnosis had the way paved for it by habitual reveries and that it was fully established by an affect of protracted anxiety, which, indeed, would itself be the basis for a hypnoid state. It seems not improbable that this process holds good fairly generally.

A great variety of states lead to 'absence of mind' but only a few of them predispose to autohypnosis or pass over immediately into it. An investigator who is deep in a problem is also no doubt anaesthetic to a certain degree, and he has large groups of sensations of which he forms no conscious perception; and the same is true of anyone who is using his creative imagination actively (cf. Anna O.'s 'private theatre' [p. 20 above]). But in such states energetic mental work is carried on, and the excitation of the nervous system which is liberated is used up in this work. In states of abstraction and dreaminess, on the other hand, intracerebral excitation sinks below its clear waking level. These states border on sleepiness and pass over into sleep. If during such a state of absorption, and while the flow of ideas is inhibited, a group of affectively coloured ideas is active, it creates a high level of intracerebral excitation which is not used up by mental work and is at the disposal of abnormal functioning, such as conversion.

Thus neither 'absence of mind' during energetic work nor unemotional twilight states are pathogenic; on the other hand, reveries that are filled with emotion and states of fatigue arising from protracted affects *are* pathogenic. The broodings of a care-ridden man, the anxiety of a person watching at the sick-bed of someone dear to him, the daydreams of a lover – these are states of this second kind. Concentration on the

affective group of ideas begins by producing 'absence of mind'. The flow of ideas grows gradually slower and at last almost stagnates; but the affective idea and its affect remain active, and so consequently does the great quantity of excitation which is not being used up functionally. The similarity between this situation and the determinants of hypnosis seems unmistakable. The subject who is to be hypnotized must not really go to sleep, that is to say, his intracerebral excitation must not sink to the level of sleep; but his flow of ideas must be inhibited. When this is so, the whole mass of excitation is at the disposal of the suggested idea.

This is the way in which pathogenic autohypnosis would seem to come about in some people – by affect being introduced into a habitual reverie. [219] This is perhaps one of the reasons why in the anamnesis of hysteria we so often come across the two great pathogenic factors of being in love and sick-nursing. In the former, the subject's longing thoughts about his absent loved one create in him a 'rapt' state of mind, cause his real environment to grow dim, and then bring his thinking to a standstill charged with affect; while in sick-nursing the quiet by which the subject is surrounded, his concentration on an object, his attention fixed on the patient's breathing – all this sets up precisely the conditions demanded by many hypnotic procedures and fills the twilight state produced in this way with the affect of anxiety. It is possible that these states differ only quantitatively from true autohypnoses and that they pass over into them.

Once this has happened, the hypnosis-like state is repeated again and again when the same circumstances arise; and the subject, instead of the normal *two* conditions of mind, has three: waking, sleeping and the hypnoid state. We find the same thing happening when deep artificial hypnosis has been frequently brought on.

I cannot say whether spontaneous hypnotic states may also be generated without an affect intervening in this way, as a result of an innate disposition; but I consider it very probable. When we see the difference in susceptibility to artificial hypnosis both among healthy and sick people and how easily it is brought on in some, it seems reasonable to suppose that in such people it can also appear spontaneously. And a disposition for this is perhaps necessary before a reverie can turn into an autohypnosis. I am therefore far from attributing to all hysterical patients the generating mechanism which we have been taught by Anna O.

I speak of hypnoid states rather than of hypnosis itself because it is so difficult to make a clear demarcation of these states, which play such an important part in the genesis of hysteria. We do not know whether reveries, which were described above as preliminary stages of autohypnosis,

may not themselves be able to produce the same pathological effect as autohypnosis, and whether the same may not also be true of a protracted affect of anxiety. It is certainly true of fright. Since fright inhibits the flow of ideas at the same time at which an affective idea (of danger) is very
[220] active, it offers a complete parallel to a reverie charged with affect; and since the recollection of the affective idea, which is constantly being renewed, keeps on re-establishing this state of mind, 'hypnoid fright' comes into being, in which conversion is either brought about or stabilized. Here we have the incubation stage of 'traumatic hysteria' in the strict sense of the words.

In view of the fact that states of mind which are so different though they agree with one another in the most important respect can be classed with autohypnosis, it seems desirable to adopt the expression 'hypnoid', which lays stress on this internal similarity. It sums up the view put forward by Moebius in the passage quoted above [pp. 191–2]. Most of all, however, it points to autohypnosis itself, the importance of which in the genesis of hysterical phenomena rests on the fact that it makes conversion easier and protects (by amnesia) the converted ideas from wearing away – a protection which leads, ultimately, to an increase in the psychical splitting.

If a somatic symptom is caused by an idea and is repeatedly set going by it, we should expect that intelligent patients capable of self-observation would be conscious of the connection; they would know by experience that the somatic phenomenon appeared at the same time as the memory of a particular event. The underlying causal nexus is, it is true, unknown to them; but all of us always know what the idea is which makes us cry or laugh or blush, even though we have not the slightest understanding of the nervous mechanism of these ideogenic phenomena. Sometimes patients do really observe the connection and are conscious of it. For instance, a woman may say that her mild hysterical attack (trembling and palpitations, perhaps) comes from some great emotional disturbance and is repeated when, and only when, some event reminds her of it. But this is not the case with very many or indeed the majority of hysterical symptoms. Even intelligent patients are unaware that their symptoms arise as the result of an idea and regard them as physical phenomena on their own account. If it were otherwise the psychical theory of hysteria must already have reached a respectable age.

It would be plausible to believe that, though the symptoms in question were ideogenic in the first instance, the repetition of them has, to use

Romberg's phrase [1840, 192], 'imprinted' them into the body, and they would now no longer be based on a psychical process but on modifications in the nervous system which have occurred in the meantime: they would have become self-sufficient, genuinely somatic symptoms. [221]

This view is in itself neither untenable nor improbable. But I believe that the new light which our observations have thrown on the theory of hysteria lies precisely in its having shown that this view is inadequate to meet the facts, at any rate in many instances. We have seen that hysterical symptoms of the most various kinds which have lasted for many years 'immediately and permanently disappeared when we had succeeded in bringing clearly to light the memory of the event by which it was provoked and in arousing its accompanying affect, and when the patient had described that event in the greatest possible detail and had put the affect into words' [p. 6 above]. The case histories which have been reported in these pages provide some pieces of evidence in support of these assertions. 'We may reverse the dictum "*cessante causa cessat effectus*" ["when the cause ceases the effect ceases"], and conclude from these observations that the determining process' (that is, the recollection of it) 'continues to operate . . . for years – not indirectly, through a chain of intermediate causal links, but as a *directly* releasing cause – just as a psychical pain that is remembered in waking consciousness still provokes a lachrymal secretion long after the event. Hysterics suffer mainly from reminiscences' [p. 7]. But if this is so – if the memory of the psychical trauma must be regarded as operating as a contemporary agent, like a foreign body, long after its forcible entrance, and if nevertheless the patient has no consciousness of such memories or their emergence – then we must admit that *unconscious ideas exist and are operative*.

Moreover, when we come to analyse hysterical phenomena we do not only find such unconscious ideas *in isolation*. We must recognize the fact that in reality, as has been shown by the valuable work carried out by French investigators, large complexes of ideas and involved psychical processes with important consequences remain completely unconscious in a number of patients and coexist with conscious mental life; we must recognize that there is such a thing as a splitting of psychical activity, and that this is of fundamental value for our understanding of complicated hysterias.

I may perhaps be allowed to explore this difficult and obscure region rather more fully. The need to establish the meaning of the terminology that has been used may to some extent excuse the theoretical discussion which follows. [222]

(5) UNCONSCIOUS IDEAS AND IDEAS INADMISSIBLE TO CONSCIOUSNESS – SPLITTING OF THE MIND

We call those ideas conscious which we are aware of. There exists in human beings the strange fact of self-consciousness. We are able to view and observe, as though they were objects, ideas that emerge in us and succeed one another. This does not happen always, since occasions for self-observation are rare. But the capacity for it is present in everyone, for everyone can say: 'I thought this or that.' We describe as conscious those ideas which we observe as active in us, or which we should so observe if we attended to them. At any given moment of time there are very few of them; and if others, apart from those, should be current at the time, we should have to call them *unconscious* ideas.

It hardly seems necessary any longer to argue in favour of the existence of current ideas that are unconscious or subconscious.[1] They are among the commonest facts of everyday life. If I have forgotten to make one of my medical visits, I have feelings of lively unrest. I know from experience what this feeling means: that I have forgotten something. I search my memories in vain; I fail to discover the cause, till suddenly, hours later perhaps, it enters my consciousness. But I have been uneasy the whole time. Accordingly, the idea of the visit has been all the time operative, that is to say present, but not in my consciousness. Or again, a busy man may have been annoyed by something one morning. He is entirely absorbed by his office work; while he is doing it his conscious thoughts are fully occupied, and he gives no thought to his annoyance. But his decisions are influenced by it and he may well say 'no' where he would otherwise have said 'yes'. So in spite of everything this memory is operative, that is to say present. A great deal of what we describe as 'mood' comes from sources of this kind, from ideas that exist and are operative
[223] beneath the threshold of consciousness. Indeed, the whole conduct of our life is constantly influenced by subconscious ideas. We can see every day how, where there is mental degeneration, as for instance in the initial stages of general paralysis,[2] the inhibitions which normally restrain certain actions become weaker and disappear. But the patient who now makes indecent jokes in the presence of women was not, in his healthy days, prevented from doing so by conscious memories and reflections; he avoided it 'instinctively' ['*instinktiv*'] and 'automatically' – that is to say, he was restrained by ideas which were called up by the impulse to behave

1 [See footnote 2, p. 41 above.]

2 [*Neurosyphilis*.]

in this way, but which remained beneath the threshold of consciousness, though they nevertheless inhibited the impulse. – All intuitive activity is directed by ideas which are to a large extent subconscious. For only the clearest and most intense ideas are perceived by self-consciousness, while the great mass of current but weaker ideas remains unconscious.

The objections that are raised against 'unconscious ideas' existing and being operative seem for the most part to be juggling with words. No doubt 'idea' ['*Vorstellung*'] is a word belonging to the terminology of conscious thinking, and 'unconscious idea' is therefore a self-contradictory expression. But the physical process which underlies an idea is the same in content and form (though not in quantity) whether the idea rises above the threshold of consciousness or remains beneath it. It would only be necessary to construct some such term as 'ideational substratum' in order to avoid the contradiction and to counter the objection.

Thus there seems to be no theoretical difficulty in also recognizing unconscious ideas as causes of pathological phenomena. But if we go into the matter more closely we come upon other difficulties. As a rule, when the intensity of an unconscious idea increases it enters consciousness *ipso facto*. Only when its intensity is slight does it remain unconscious. What seems hard to understand is how an idea can be sufficiently intense to provoke a lively motor act, for instance, and at the same time not intense enough to become conscious.

I have already [p. 183 f. above] mentioned a view which should not, perhaps, be dismissed out of hand. On this view the clarity of our ideas, and consequently their capacity for being observed by our self-consciousness – that is, for being conscious – is determined, among other things, by the feelings of pleasure or unpleasure [*Lust- oder Unlust-gefühle*] which they arouse, by their quota of affect.[1] When an idea immediately produces lively somatic consequences, this implies that the excitation engendered by it flows off into the paths concerned in these consequences, instead of, as would happen otherwise, becoming diffused in the brain; and precisely *because* this idea has physical consequences, because its sums of psychical stimuli have been 'converted' into somatic ones, it loses the clarity which would otherwise have marked it out in the stream of ideas. Instead of this it is lost among the rest. [224]

1 [*Affekt*. Breuer seems here to be using the term, in a sense quite exceptional in the present volume (though one sometimes employed by other psychologists), to indicate specifically feelings of pleasure and unpleasure. The same word '*Affektwert*' is used by him above (p. 190 f.) in his regular sense of an unspecified quantum of emotional feeling.]

Suppose, for instance, that someone has had a violent affect during a meal and has not 'abreacted' it. When subsequently he attempts to eat he is overtaken by choking and vomiting and these seem to him purely somatic symptoms. His hysterical vomiting continues for some considerable time. It disappears after the affect has been revived, described and reacted to under hypnosis. There can be no doubt that every attempt to eat called up the memory concerned. This memory started the vomiting but did not appear clearly in consciousness, because it was now without affect, whereas the vomiting absorbed the attention completely.

It is conceivable that the reason which has just been given explains why *some* ideas that release hysterical phenomena are not recognized as their causes. But this reason – the fact that ideas that have lost their affect because they have been converted are overlooked – cannot possibly explain why, in other cases, ideational complexes that are anything but devoid of affect do not enter consciousness. Numerous examples of this are to be found in our case histories.

In patients like these we found that it was the rule for the emotional disturbance – apprehensiveness, angry irritability, grief – to precede the appearance of the somatic symptom or to follow it immediately, and to increase, either until it was cleared up by being given utterance in words or until the affect and the somatic phenomenon gradually disappeared again. Where the former happened the quality of the affect always
[225] became quite understandable, even though its intensity could not fail to seem to a normal person (and to the patient himself, after it had been cleared up) to be out of all proportion. These, then, were ideas which were intense enough not merely to cause powerful somatic phenomena but also to call out the appropriate affect and to influence the course of association by bringing allied ideas into prominence – but which, in spite of all this, remained outside consciousness themselves. In order to bring them into consciousness hypnosis was necessary (as in Case Histories 1 and 2), or (as in Case Histories 4 and 5) a laborious search had to be made with strenuous help from the physician.

Ideas such as these which, though current, are unconscious, not because of their relatively small degree of liveliness, but in spite of their great intensity, may be described as ideas that are 'inadmissible to consciousness'.[1]

1 This expression ['*Bewusstseinsunfähig*'] is not unambiguous and for that reason leaves much to be desired. It is, however, constructed on the analogy of '*Hoffähig*' ['admissible to court', 'having the entrée'] and may in the meantime be used for lack of a better term. [Though on the analogy of '*Hoffähig*' the word is here translated '*inadmissible* to consciousness', its literal meaning is '*incapable* of consciousness'. It could equally well be translated 'incapable of being (or becoming) conscious'. The word was adopted by Freud and frequently used by him, and the context then often calls for one of these other renderings.]

The existence of ideas of this kind that are inadmissible to consciousness is pathological. In normal people all ideas that can become current at all enter consciousness as well if they are sufficiently intense. In our patients we find a large complex of ideas that are admissible to consciousness existing side by side with a smaller complex of ideas that are not. Thus in them the field of ideational psychical activity does not coincide with potential consciousness. The latter is more restricted than the former. Their psychical ideational activity is divided into a conscious and an unconscious part, and their ideas are divided into some that are admissible and some that are inadmissible to consciousness. We cannot, therefore, speak of a splitting of consciousness, though we can of a *splitting of the mind*.

Conversely, these subconscious ideas cannot be influenced or corrected by conscious thought. They are very often concerned with experiences which have in the meantime lost their meaning – dread of events which did not occur, fright that turned to laughter or joy after [226]
a rescue. Such subsequent developments deprive the memory of all its affect so far as consciousness is concerned; but they leave the subconscious idea, which provokes somatic phenomena, completely untouched.

Perhaps I may be allowed to quote another example. A young married woman was for some time very much worried about her younger sister's future. As a result of this her period, normally regular, lasted for two weeks; she was tender in the left hypogastrium, and twice she found herself lying stiff on the floor, coming out of a 'faint'. There followed an ovarian neuralgia on the left side, with signs of a severe peritonitis. The absence of fever, and a contracture of the left leg (and of her back), showed that the illness was a *pseudo*-peritonitis; and when, a few years later, the patient died and an autopsy was performed, all that was found was a 'microcystic degeneration' of *both* ovaries without any traces of an old peritonitis. The severe symptoms disappeared by degrees and left behind an ovarian neuralgia, a contracture of the muscles of the back, so that her trunk was as stiff as a board, and a contracture of the left leg. The latter was got rid of under hypnosis by direct suggestion. The contracture of her back was unaffected by this. Meanwhile her younger sister's difficulties had been completely smoothed out and all her fears on that score had vanished. But the hysterical phenomena, which could only have been derived from them, persisted unaltered. It was tempting to suppose that what we were faced with were changes in innervation, which had

assumed an independent status and were no longer attached to the idea that had caused them. But after the patient had been compelled under hypnosis to tell the whole story up to the time when she had fallen ill of 'peritonitis' – which she did most unwillingly – she immediately sat up in bed without assistance, and the contracture of her back disappeared for ever. (Her ovarian neuralgia, which was undoubtedly much older in its origin, remained unaffected.) Thus we see that her pathogenic anxious idea had persisted in active operation for months on end, and that it had been completely inaccessible to any correction by actual events.

If we are obliged to recognize the existence of ideational complexes that never enter consciousness and are not influenced by conscious thought, we shall have admitted that, even in such simple cases of hysteria as the
[227] one I have just described, there is a splitting of the mind into two relatively independent portions. I do not assert that everything that we call hysterical has a splitting of this kind as its basis and necessary condition; but I *do* assert that 'the splitting of psychical activity which is so striking in the well-known cases in the form of "*double conscience*" is present to a rudimentary degree in every major hysteria', and that 'the liability and tendency to such a dissociation is the basic phenomenon of this neurosis'.[1]

But before entering into a discussion of this subject, I must add a comment with regard to the unconscious ideas which produce somatic effects. Many hysterical phenomena last continuously for a long time, like the contracture in the case described above. Should we and may we suppose that during all this time the causative idea is perpetually active and currently present? I think so. It is true that in healthy people we see their psychical activity going forward to the accompaniment of a rapid change of ideas. But we find sufferers from severe melancholia immersed continuously for long periods in the same distressing idea which is perpetually active and present. Indeed, we may well believe that even when a healthy person has a great care on his mind it is present all the time, since it governs his facial expression even when his consciousness is filled with other thoughts. But the portion of psychical activity which is separated off in hysterical subjects and which we think of as filled with unconscious ideas contains as a rule such a meagre store of them and is so inaccessible to interchange with external impressions that it is easy to believe that a single idea can be permanently active in it.

1 [This passage, which is in inverted commas in the original but has no page reference, is a slightly modified version of a sentence which can be found in italics on p. 11 of the 'Preliminary Communication' above. At that point Breuer & Freud still spoke of a 'splitting of consciousness' rather than 'splitting of psychical activity'.]

If it seems to us, as it does to Binet and Janet, that what lies at the centre of hysteria is a splitting off of a portion of psychical activity, it is our duty to be as clear as possible on this subject. It is only too easy to fall into a habit of thought which assumes that every substantive has a substance behind it – which gradually comes to regard 'consciousness' as standing for some actual thing; and when we have become accustomed to make use metaphorically of spatial relations, as in the term 'subconsciousness', [228] we find as time goes on that we have actually formed an idea which has lost its metaphorical nature and which we can manipulate easily as though it was real. Our mythology is then complete.

All our thinking tends to be accompanied and aided by spatial ideas, and we talk in spatial metaphors. Thus when we speak of ideas which are found in the region of clear consciousness and of unconscious ones which never enter the full light of self-consciousness, we almost inevitably form pictures of a tree with its trunk in daylight and its roots in darkness, or of a building with its dark underground cellars. If, however, we constantly bear in mind that all such spatial relations are metaphorical and do not allow ourselves to be misled into supposing that these relations are literally present in the brain, we may nevertheless speak of a consciousness and a subconsciousness. But only on this condition.

We shall be safe from the danger of allowing ourselves to be tricked by our own figures of speech if we always remember that after all it is in the same brain, and most probably in the same cerebral cortex, that conscious and unconscious ideas alike have their origin.[1] How this is possible we cannot say. But then we know so little of the psychical activity of the cerebral cortex that one puzzling complication the more scarcely increases our limitless ignorance. We must take it as a fact that in hysterical patients a part of their psychical activity is inaccessible to perception by the self-consciousness of the waking individual and that their mind is thus split.

A universally known example of a division of psychical activity like this is to be seen in hysterical attacks in some of their forms and stages. At their beginning, conscious thought is often extinguished; but afterwards it gradually awakens. Many intelligent patients admit that their conscious ego [*Ich*][T] was quite lucid during the attack and looked on with curiosity and surprise at all the mad things they did and said. Such patients have, furthermore, the (erroneous) belief that with a little goodwill they could have inhibited the attack, and they are inclined to blame

1 [Cf. some remarks to a similar effect in Freud's Preface to his translation of Bernheim's *De la suggestion* (Freud, 1888–89*a*), *RSE*, **1**, 90.]

themselves for it. 'They need not have behaved like that.' (Their self-
[229] reproaches of being guilty of simulation are also to a great extent based on this feeling.)[1] But when the next attack comes on, the conscious ego is as little able to control what happens as in earlier ones. – Here we have a situation in which the thought and ideation of the conscious waking ego stands alongside of the ideas which normally reside in the darkness of the unconscious but which have now gained control over the muscular apparatus and over speech, and indeed even over a large part of ideational activity itself: the splitting of the mind is manifest.

It may be remarked that the findings of Binet and Janet deserve to be described as a splitting not merely of psychical activity but of consciousness. As we know, these observers have succeeded in getting into contact with their patients' 'subconsciousness', with the portion of psychical activity of which the conscious waking ego knows nothing; and they have been able in some of their cases to demonstrate the presence of all the psychical functions, including self-consciousness, in that portion, since it has access to the memory of earlier psychical events. This half of a mind is therefore quite complete and conscious in itself. In our cases the part of the mind which is split off is 'thrust into darkness',[2] as the Titans are imprisoned in the crater of Etna, and can shake the earth but can never emerge into the light of day. In Janet's cases the division of the realm of the mind has been a total one. Nevertheless, there is still inequality in status. But this, too, disappears when the two halves of consciousness alternate, as they do in the well-known cases of *double conscience*, and when they do not differ in their functional capability.

But let us return to the ideas which we have shown in our patients as the causes of their hysterical phenomena. It is far from being possible for us simply to describe them all as being 'unconscious' and 'inadmissible to consciousness'. They form an almost unbroken scale, passing through every gradation of vagueness and obscurity, between perfectly conscious ideas which release an unusual reflex and those which never enter consciousness in waking life but only in hypnosis. In spite of this, we regard
[230] it as established that a splitting of psychical activity occurs in the more severe degrees of hysteria and that it alone seems to make a psychical theory of the illness possible.

1 [These points are exemplified in the case of Anna O. See p. 42 above.]

2 ['*In die Finsternis gebracht*', a phrase used by Mephistopheles of himself, in *Faust*, Part I (Scene 4).]

What, then, can be asserted or suspected with probability about the causes and origin of this phenomenon?

Janet, to whom the theory of hysteria owes so very much and with whom we are in agreement in most respects, has expressed a view on this point which we are unable to accept.

Janet's view is the following.[1] He considers that the 'splitting of a personality' rests on an innate psychological weakness ('*insuffisance psychologique*'). All normal mental activity presupposes a certain capacity for 'synthesis', the ability to unite several ideas into a complex. The combination of the various sense perceptions into a picture of the environment is already a synthetic activity of this kind. This mental function is found to be far below the normal in hysterical patients. If a normal person's attention is directed as fully as possible upon some point, e.g. upon a perception by a single sense, it is true that he temporarily loses the capacity to apperceive impressions from the other senses – that is, to take them up into his conscious thought. But in hysterical subjects this happens without any special concentration of the attention. As soon as they perceive anything they are inaccessible to other sense perceptions. Indeed, they are not even in a position to take in together a number of impressions coming from a *single* sense. They can, for instance, only apperceive tactile sensations in one half of the body; those from the other side reach the centre and are used for the coordination of movement, but are not apperceived. A person like this is hemianaesthetic. In normal people, an idea calls into consciousness a great number of others by association; these may be related to the first one, for instance, in a confirmatory or an inhibiting manner, and only the most vivid ideas are so extremely powerful that their associations remain below the threshold of consciousness. In hysterical people this is always the case. Every idea takes possession of the whole of their limited mental activity, and this accounts for their [231]
excessive affectivity. This characteristic of their mind is described by Janet as the 'restriction of the field of consciousness' of hysterical patients, on the analogy of a 'restriction of the field of vision'. For the most part the sense impressions that are not apperceived and the ideas that are aroused but do not enter consciousness cease without producing further consequences. Sometimes, however, they accumulate and

1 [The account of Janet's views which follows seems to be derived principally from the concluding chapter of Janet, 1894. This chapter was a reprint of a paper published in the *Archives de Neurologie* in 1893 (June and July) which was largely concerned with the Breuer & Freud 'Preliminary Communication'. Cf. also p. 92 above.]

form complexes[1] – mental strata withdrawn from consciousness; they form a subconsciousness. Hysteria, which is essentially based on this splitting of the mind, is a '*maladie par faiblesse*' ['disease due to weakness'], and that is why it develops most readily when a mind which is innately weak is submitted to influences that weaken it still further or is faced with heavy demands in relation to which its weakness stands out still more.

Janet's opinions, as thus summarized, already give his answer to the important question as to the disposition to hysteria – as to the nature of the *typus hystericus* (taking the term in the sense in which we speak of a *typus phthisicus*, by which we understand the long narrow thorax, the small heart, etc.). Janet regards a particular form of congenital mental weakness as the disposition to hysteria. In reply, we should like to formulate our own view briefly as follows. It is not the case that the splitting of consciousness occurs because the patients are weak-minded; they appear to be weak-minded because their mental activity is divided and only a part of its capacity is at the disposal of their conscious thought. We cannot regard mental weakness as the *typus hystericus*, as the essence of the disposition to hysteria.

An example makes plain what is intended by the first of these two sentences. We were frequently able to observe the following course of events with one of our patients (Frau Cäcilie M.). While she was feeling comparatively well a hysterical symptom would appear – a tormenting, obsessive hallucination, a neuralgia, or something of the kind – and would for some time increase in intensity. Simultaneously the patient's mental capacity would continuously decrease, and after a few days any uninitiated observer would have been bound to call her weak-minded. She would then be relieved of the unconscious idea (the memory of a [232] psychical trauma, often belonging to the remote past), either by the physician under hypnosis or by her suddenly describing the event in a state of agitation and to the accompaniment of a lively emotion. When this had happened she did not merely become quiet and cheerful and free from the tormenting symptom; it was always astonishing to observe the width and clarity of her intellect and the acuteness of her understanding and judgement. Chess, which she played excellently, was a favourite occupation of hers, and she enjoyed playing two games at a time, which

1 [This use of the word 'complex' seems to come very close to that which Jung is generally regarded as having introduced some ten years later. Cf. Part II of Freud's 'History of the Psychoanalytic Movement' (1914*d*), *RSE*, **14**, 25. Freud uses the term in a similar sense in the 'Project' already (ibid., **1**, 402). The phrases 'complex of ideas' and 'ideational complex', which have a more general sense, are used throughout these *Studies*.]

can scarcely be regarded as indicating a lack of mental synthesis.[1] It was impossible to escape the impression that during a course of events such as we have just described the unconscious idea drew to itself an ever-increasing portion of her psychical activity and that the more this happened the smaller became the part played by conscious thought, till it was reduced to total imbecility; but that when, to use the remarkably apt Viennese expression, she was '*beisammen*' [literally 'together', meaning 'in one's right mind'], she possessed quite remarkable mental powers.

As a comparable state in normal people we would adduce, not concentration of attention, but *preoccupation*. If someone is 'preoccupied' by some vivid idea, such as a worry, his mental capacity is similarly reduced.

Every observer is largely under the influence of the subjects of his observation, and we are inclined to believe that Janet's views were mainly formed in the course of a detailed study of the feeble-minded hysterical patients who are to be found in hospitals or institutions because they have not been able to hold their own in life on account of their illness and the mental weakness caused by it. Our own observations, carried out on educated hysterical patients, have forced us to take an essentially different view of their minds. In our opinion 'among hysterics may be found people of the clearest intellect, strongest will, greatest character and highest critical power' [cf. p. 12 above]. No amount of genuine, solid mental endowment is excluded by hysteria, though actual achievements are often made impossible by the illness. After all, the patron saint of hysteria, St Theresa, was a woman of genius with great practical capacity.

But, on the other hand, no degree of silliness, incompetence and weakness of will is a protection against hysteria. Even if we disregard [233]
what is merely a *result* of the illness, we must recognize the type of feeble-minded hysteric as a common one. Yet even so, what we find here is not torpid, phlegmatic stupidity but an excessive degree of mental mobility which leads to inefficiency. I shall discuss later the question of innate disposition. Here I merely propose to show that Janet's opinion that mental weakness is in any way at the root of hysteria and splitting of the mind is untenable.[2]

In complete opposition to Janet's views, I believe that in a great many cases what underlies dissociation is an *excess* of efficiency, the habitual

1 [She famously had a professional chess player waiting outside her room all night, in case of need.]

2 [Cf. in this connection Freud's remarks on Frau Emmy von N. (p. 91 ff. above) and his related polemic against Janet.]

coexistence of two heterogeneous trains of ideas. It has frequently been pointed out that we are often not merely 'mechanically' active while our conscious thought is occupied by trains of ideas which have nothing in common with our activity, but that we are also capable of what is undoubtedly psychical functioning while our thoughts are 'busy elsewhere' – as, for instance, when we read aloud correctly and with the appropriate intonation, but afterwards have not the slightest idea of what we have been reading.

There are no doubt a whole number of activities, from mechanical ones such as knitting or playing scales, to some requiring at least a small degree of mental functioning, all of which[1] are performed by many people with only half their mind on them. This is specially true of people who are of a very lively disposition, to whom monotonous, simple and uninteresting occupation is a torture, and who actually begin by deliberately amusing themselves with thinking of something different (cf. Anna O.'s 'private theatre' [p. 20 above]). Another situation, but a similar one, occurs when an interesting set of ideas, derived for instance from books or plays, forces itself upon the subject's attention and intrudes into his thoughts. This intrusion is still more vigorous if the extraneous set of ideas is strongly coloured with affect (e.g. worry or the longing of someone in love). We then have the state of preoccupation that I have touched upon above, which, however, does not prevent many people from performing fairly complicated actions. Social circumstances often necessitate a duplication of this kind even when the thoughts involved are of an exacting kind, as for instance when a woman who is in the throes of
[234] extreme worry or of passionate excitement carries out her social duties and the functions of an affable hostess. We all of us manage minor achievements of this kind in the course of our work; and self-observation seems always to show that the affective group of ideas are not merely aroused from time to time by association but are present in the mind all the time and enter consciousness unless it is taken up with some external impression or act of will.

Even in people who do not habitually allow daydreams to pass through their minds alongside their usual activity, some situations give rise during considerable periods of time to this simultaneous existence of changing impressions and reactions from external life on the one hand, and an affectively coloured group of ideas on the other. *Post equitem sedet atra cura* ['black care sits behind the rider'].[2] Among these situations the most

1 [*welche alle*. So in the first German edition, whereafter the '*alle*' ('all of') was dropped.]

2 [Horace, *Odes*, III, 1.]

prominent are those of looking after someone dear to us who is ill, and of being in love. Experience shows that sick-nursing and sexual affects also play the principal part in the majority of the more closely analysed case histories of hysterical patients.

I suspect that the duplication of psychical functioning, whether this is habitual or caused by emotional situations in life, acts as a substantial *predisposition* to a genuine pathological splitting of the mind. This duplication passes over into the latter state if the content of the two coexisting sets of ideas is no longer of the same kind, if one of them contains ideas which are inadmissible to consciousness – which have been fended off, that is, or have arisen from hypnoid states. When this is so, it is impossible for the two temporarily divided streams to reunite, as is constantly happening in healthy people, and a region of unconscious psychical activity becomes permanently split off. This hysterical splitting of the mind stands in the same relation to the 'double ego' of a healthy person as does the hypnoid state to a normal reverie. In this latter contrast what determines the pathological quality is amnesia, and in the former what determines it is the inadmissibility of the ideas to consciousness.

Our first case history, that of Anna O., to which I am obliged to keep on returning, affords a clear insight into what happens. The girl was in the habit, while she was in perfect health, of allowing trains of imaginative ideas to pass through her mind during her ordinary occupations. [235]
While she was in a situation that favoured autohypnosis, the affect of anxiety entered into her reverie and created a hypnoid state for which she had amnesia. This was repeated on different occasions and its ideational content gradually became richer and richer; but it continued to alternate with states of completely normal waking thought. After four months the hypnoid state gained entire control of the patient. The separate attacks ran into one another and thus an *état de mal* arose, an acute hysteria of the most severe type. This lasted for several months in various forms (the period of somnambulism); it was then forcibly interrupted [p. 24 f. above], and thereafter alternated once again with normal psychical behaviour. But even during her normal behaviour there was a persistence of somatic and psychical phenomena (contractures, hemianaesthesia and changes in speech) of which in this case we know as a fact that they were based on ideas belonging to the hypnoid state. This proves that even during her normal behaviour the ideational complex belonging to the hypnoid state, the 'subconsciousness', was in existence and that the split in her mind persisted.

I have no second example to offer of a similar course of development. I think, however, that the case throws some light also on the growth of *traumatic* neuroses. During the first few days after the traumatic event, the state of hypnoid fright is repeated every time the event is recalled. While this state recurs more and more often, its intensity so far diminishes that it no longer *alternates* with waking thought but only exists side by side with it. It now becomes continuous, and the somatic symptoms, which earlier were only present during the attack of fright, acquire a permanent existence. I can, however, only *suspect* that this is what happens, as I have never analysed a case of this kind.

Freud's observations and analyses show that the splitting of the mind can also be caused by 'defence' [*Abwehr*], by the deliberate deflection of consciousness from distressing ideas: only, however, in some people, to whom we must therefore ascribe a mental idiosyncrasy. In normal people, such ideas are either successfully suppressed, in which case they vanish completely, or they are not, in which case they keep on emerging in consciousness. I cannot tell what the nature of this idiosyncrasy is. I only
[236] venture to suggest that the assistance of the hypnoid state is necessary if defence is to result not merely in single converted ideas being made into unconscious ones, but in a genuine splitting of the mind. Autohypnosis has, so to speak, created the space or region of unconscious psychical activity into which the ideas which are fended off [*abgewehrten*] are driven. But, however this may be, the fact of the pathogenic significance of 'defence' is one that we must recognize.

I do not think, however, that the genesis of splitting of the mind is anything like covered by the half-understood processes that we have discussed. Thus, in their initial stages hysterias of a severe degree usually exhibit for a time a syndrome that may be described as acute hysteria. (In the anamnesis of male cases of hysteria we generally come across this form of illness represented as being 'encephalitis'; in female cases ovarian neuralgia leads to a diagnosis of 'peritonitis'.) In this acute stage of hysteria psychotic traits are very distinct, such as manic and angry states of excitement, rapidly changing hysterical phenomena, hallucinations, and so on. In states of this kind the splitting of the mind may perhaps take place in a different manner from that which we have tried to describe above. Perhaps the whole of this stage is to be regarded as a long hypnoid state, the residues of which provide the nucleus of the unconscious ideational complex, while waking thought is amnesic for it. Since we are for the most part ignorant of the causes that lead to an acute hysteria of this kind (for I do not venture to regard the course of events with Anna O. as

having general application), there would seem to be another sort of psychical splitting which, in contrast to those discussed above, might be termed irrational.[1] And no doubt yet other forms of this process exist, which are still concealed from our young psychological science; for it is certain that we have only taken the first steps in this region of knowledge, and our present views will be substantially altered by further observations.

Let us now enquire what the knowledge of splitting of the mind that has been gained during the last few years has achieved towards an understanding of hysteria. It seems to have been great in amount and in importance. [237]

These discoveries have in the first place made it possible for what are apparently purely somatic symptoms to be traced back to ideas, which, however, are not discoverable in the patients' consciousness. (It is unnecessary to enter into this again.) In the second place, they have taught us to understand hysterical attacks, in part at least, as being products of an unconscious ideational complex. (Cf. Charcot.)[2] But, besides this, they have also explained some of the psychical characteristics of hysteria, and this point perhaps deserves a more detailed discussion.

It is true that 'unconscious ideas' never, or only rarely and with difficulty, enter waking thought; but they influence it. They do so, first, through their consequences – when, for instance, a patient is tormented by a hallucination which is totally unintelligible and senseless, but whose meaning and motivation become clear under hypnosis. Further, they influence association by making certain ideas more vivid than they would have been if they had not been thus reinforced from the unconscious. So particular groups of ideas constantly force themselves on the patient with a certain amount of compulsion and he is obliged to think of them. (The case is similar with Janet's hemianaesthetic patients. When their anaesthetic hand is repeatedly touched they feel nothing; but when they are told to name any number they like, they always choose the one corresponding to the number of times they have been touched.) Again, unconscious ideas govern the patient's emotional tone, his state of feeling. When, in the course of unrolling her memories, Anna O.

1 I must, however, point out that precisely in the best-known and clearest example of major hysteria with manifest '*double conscience*' – precisely in the case of Anna O. – no residue of the acute stage was carried over into the chronic one, and all the phenomena of the latter had already been produced during the 'incubation period' in hypnoid and affective states.

2 [See p. 12 f. above.]

approached an event which had originally been bound up with a lively affect, the corresponding feeling made its appearance several days in advance and before the recollection appeared clearly even in her hypnotic consciousness.

This makes the patients' 'moods' [*'Launen'*] intelligible – their inexplicable, unreasonable changes of feeling which seem to waking thought without motive. The impressionability of hysterical patients is indeed to a large extent determined simply by their innate excitability; but the lively affects into which they are thrown by relatively trivial causes become more intelligible if we reflect that the 'split-off mind' acts like a
[238] sounding-board to the note of a tuning fork. Any event that provokes unconscious memories liberates the whole affective force of these ideas that have not undergone a wearing away, and the affect that is called up is then quite out of proportion to any that would have arisen in the conscious mind alone.

I have spoken above [p. 206 f.] of a patient whose psychical functioning always stood in inverse ratio to the vividness of her unconscious ideas. The diminution of her conscious thinking was based partly, but only partly, on a peculiar kind of abstraction. After each of her momentary '*absences*' – and these were constantly occurring – she did not know what she had thought of in the course of it. She oscillated between her '*conditions primes*' and '*secondes*', between the conscious and the unconscious ideational complexes. But it was not only on that account that her psychical functioning was reduced, nor on account of the affect which dominated her from the unconscious. While she was in this state her waking thought was without energy, her judgement was childish and she seemed, as I have said, positively imbecile. I believe that this was due to the fact that waking thought has less energy at its disposal if a great amount of psychical excitation is appropriated by the unconscious.

If this state of things is not merely temporary, if the split-off mind is in a *constant* state of excitation, as it was with Janet's hemianaesthetic patients – in whom, moreover, all the sensations in no less than one half of the body were perceived only by the unconscious mind – if this is the case, so little cerebral functioning is left over for waking thought that the weakness of mind which Janet describes and regards as innate is fully accounted for. There are only very few people of whom it could be said, as of Uhland's Bertrand de Born, that they never need more than half their mind.[1] Such a reduction in their psychical energy does make the majority of people weak-minded.

1 [A famous troubadour about whom Uhland wrote a ballad.]

This weakness of mind caused by a splitting of the psyche seems also to be a basis of a momentous characteristic of *some* hysterical patients – their suggestibility. (I say 'some', since it is certain that among hysterical patients are to be found people of the soundest and most critical judgement as well.)

By suggestibility we understand, in the first instance, only an inability to [239] criticize ideas and complexes of ideas (judgements) which emerge in the subject's own consciousness or are introduced into it from outside through the spoken word or through reading. All criticism of ideas like these which come freshly into consciousness is based on the fact that they awaken other ideas by association and among them some that are irreconcilable with the fresh ones. The resistance to these latter is thus dependent on the store of antagonistic ideas in potential consciousness, and the strength of the resistance corresponds to the ratio between the vividness of the fresh ideas and that of those aroused from memory. Even in normal intellects this ratio is very various. What we describe as an intellectual temperament depends on it to a great extent. A 'sanguine' man is always delighted by new people and things, and this is no doubt so because the intensity of his mnemic images is less in comparison with that of new impressions than it is in a quieter, 'phlegmatic' man. In pathological states the preponderance of fresh ideas and the lack of resistance to them increases in proportion to the fewness of the mnemic images aroused – that is, in proportion to the weakness and poorness of their associative powers. This is already what happens in sleep and dreams, in hypnosis and whenever there is a reduction in mental energy, so long as this does not also reduce the vividness of the fresh ideas.

The unconscious, split-off mind in hysteria is pre-eminently suggestible on account of the poverty and incompleteness of its ideational content. But the suggestibility of the conscious mind, too, in some hysterical patients seems to be based on this. They are excitable from their innate disposition; in them, fresh ideas are very vivid. In contrast to this, their intellectual activity proper, their associative function, is reduced, because only a part of their psychical energy is at the disposal of their waking thought, owing to a splitting off of an 'unconscious'. As a result of this their power of resistance both to auto- and allosuggestions is diminished and sometimes abolished. The suggestibility of their *will* also seems to be due to this alone. On the other hand, *hallucinatory* suggestibility, which promptly changes every idea of a sense perception into an actual perception, demands, like all hallucinations, an abnormal degree of excitability of the perceptual organ and cannot be traced back solely to a splitting of the mind.

(6) INNATE DISPOSITION – DEVELOPMENT OF HYSTERIA

[240] At almost every stage of these discussions I have been obliged to recognize that most of the phenomena which we have been endeavouring to understand can be based, among other things, on an innate idiosyncrasy. This defies any explanation that seeks to go beyond a mere statement of the facts. But the *capacity to acquire* hysteria is also undoubtedly linked with an idiosyncrasy of the person concerned, and an attempt to define it more accurately will perhaps not be entirely unprofitable.

I have explained above why I cannot accept Janet's view that the disposition to hysteria is based on innate psychical weakness. The medical practitioner who, in his capacity as family doctor, observes the members of hysterical families at all ages will certainly be inclined to regard this disposition as lying in an excess rather than in a defect. Adolescents who are later to become hysterical are for the most part lively, gifted and full of intellectual interests before they fall ill. Their energy of will is often remarkable. They include girls who get out of bed at night so as secretly to carry on some study that their parents have forbidden from fear of their overworking. The capacity for forming sound judgements is certainly not more abundant in them than in other people; but it is rare to find in them simple, dull intellectual inertia and stupidity. The overflowing productivity of their minds has led one of my friends to assert that hysterics are the flower of mankind, as sterile, no doubt, but as beautiful as double flowers.

Their liveliness and restlessness, their craving for sensations and mental activity, their intolerance of monotony and boredom, may be formulated thus: they are among those people whose nervous system while it is at rest liberates excess of excitation which needs to be made use of (cf. p. 175 f. above). During development at puberty, and in consequence of it, this original excess is supplemented by the powerful increase in excitation which arises from the awakening of sexuality, from the sex glands. From then on there is a surplus quantity of free nervous energy available for the production of pathological phenomena.

But in order for these phenomena to appear in the form of hysterical symptoms there must evidently also be another, specific idiosyncrasy in the individual concerned. For after all, the great majority of lively and
[241] excitable people do not become hysterical. I was only able, above [p. 170], to describe this idiosyncrasy in the vague and unenlightening phrase, 'abnormal excitability of the nervous system'. But it may be possible to

go further and say that this abnormality lies in the fact that in such people the excitation of the central organ can flow into the sensory nervous apparatuses which are normally accessible only to peripheral stimuli, as well as into the nervous apparatuses of the vegetative organs which are isolated from the central nervous system by powerful resistances. It may be that this idea of there being a surplus of excitation constantly present which has access to the sensory, vasomotor and visceral apparatuses already accounts for some pathological phenomena.

In people of this kind, as soon as their attention is forcibly concentrated on some part of the body, what Exner [1894, 165 ff.] speaks of as the 'facilitation by attention' in the sensory path of conduction concerned exceeds the normal amount. The free, floating excitation is, as it were, diverted into this path, and a local hyperalgesia is produced. As a result, every pain, however caused, reaches maximum intensity, every ailment is 'fearful' and 'unbearable'. Further, whereas in normal people a quantity of excitation, after cathecting a sensory path, always leaves it again, this is not so in these cases. That quantity, moreover, not only remains behind but is constantly increased by the influx of fresh excitations. A slight injury to a joint thus leads to arthralgia, and the painful sensations due to ovarian swelling lead to chronic ovarian neuralgia; and since the nervous apparatuses of the circulation are more accessible to cerebral influence than in normal people, we find nervous palpitation of the heart, a tendency to fainting, proneness to excessive blushing and turning pale, and so on.

However, it is not only in regard to *central* influences that the peripheral nervous apparatuses are more easily excitable. They also react in an excessive and perverse fashion to appropriate, functional stimuli. Palpitations follow from moderate effort no less than from emotional excitement, and the vasomotor nerves cause the arteries to contract ('dead fingers'), apart from any psychical influence. And just as a slight injury leaves behind an arthralgia, a short attack of bronchitis is followed by nervous asthma, and indigestion by frequent cardiac pains. We must accordingly recognize that accessibility to sums of excitation of central origin is no more than a special case of general abnormal excitability,[1] even though it is the most important one from the point of view of our present topic. [242]

It seems to me, therefore, that the old 'reflex theory' of these symptoms, which would perhaps be better described simply as 'nervous' ones but which form part of the empirical clinical picture of hysteria, should not be completely rejected. The vomiting, which of course accompanies

1 Oppenheim's 'instability of the molecules'. [See footnote, p. 170 above.]

the dilatation of the uterus in pregnancy, may, where there is abnormal excitability, quite well be set going in a reflex manner by trivial uterine stimuli, or perhaps even by the periodic changes in size of the ovaries. We are acquainted with so many remote effects resulting from organic changes, so many strange instances of 'referred pain', that we cannot reject the possibility that a host of nervous symptoms which are sometimes determined psychically may in other cases be remote effects of reflex action. Indeed, I venture to put forward the highly unmodern heresy that even motor weakness in a leg may sometimes be determined by a genital affection, not psychically, but by direct reflex action. I think we shall do well not to insist too much on the exclusiveness of our new discoveries or to seek to apply them in all cases.

Other forms of abnormal sensory excitability still escape our understanding completely: general analgesia, for instance, anaesthetic areas, real restriction of the field of vision, and so on. It is possible and perhaps probable that further observations will prove the psychical origin of one or other of these stigmata[1] and so explain the symptom; but this has not yet happened (for I do not venture to generalize the findings presented by our first case history), and I do not think it is justifiable to presume that this is their origin before it has been properly traced.

On the other hand, the idiosyncrasy of the nervous system and of the psyche which we have been discussing seems to explain one or two very familiar properties of many hysterical patients. The surplus of excitation which is liberated by their nervous system when in a state of rest determines their incapacity to tolerate a monotonous life and boredom – their craving for sensations which drives them, after the onset of their illness, to interrupt the monotony of their invalid life by all kinds of 'incidents',
[243] of which the most prominent are from the nature of things pathological phenomena. They are often supported in this by autosuggestion. They are led further and further along this road by their need for being ill, a remarkable trait which is as pathognomonic for hysteria as is *fear* of being ill for hypochondria.[2] I know a hysterical woman who inflicted on herself injuries which were often quite severe, merely for her own use and without those about her or her physician learning of them. If she did nothing else she used to play all kinds of tricks while she was alone in her room simply to prove to herself that she was not normal. For she had in fact a distinct feeling of not being well and could not discharge her duties satisfactorily, and she tried to justify herself in her own eyes by actions

1 [See footnote, p. 14 above.]

2 [Cf. a remark of Freud's, p. 230 below. See also pp. 293 and 303.]

such as these. Another patient, a very sick woman suffering from pathological conscientiousness and full of distrust of herself, felt every hysterical phenomenon as something guilty, because, she said, she need not have had it if she had really wanted not to. When a paresis of her legs was wrongly diagnosed as a disease of the spine she felt it as an immense relief, and when she was told that it was 'only nervous' and would pass off, that was enough to bring on severe pangs of conscience. The need to be ill arises from the patient's desire to convince herself and other people of the reality of her illness. When this need is further associated to the distress caused by the monotony of a sick-room, the inclination to produce more and more new symptoms is developed to the full.

If, however, this turns into deceitfulness and actual simulation (and I think that we now err just as far on the side of denying simulation as we used to on the side of accepting it), that is based, not on the hysterical disposition but, as Moebius has so aptly said, on its being complicated by other forms of degeneracy – by innate, moral inferiority. In just the same way the 'malicious hysteric' comes into existence when someone who is innately excitable but poor in emotion is also a victim to the egoistic stunting of character which is so easily produced by chronic ill-health. Incidentally, the 'malicious hysteric' is scarcely commoner than the malicious patient in the later stages of tabes.

A surplus of excitation also gives rise to pathological phenomena in the motor sphere. Children having this characteristic very easily develop tic-like movements. These may be started in the first instance by some [244]
sensation in the eyes or face or by an uncomfortable article of clothing, but they become permanent unless they are promptly checked. The reflex paths are very easily and quickly dug in deep.

Nor can the possibility be dismissed of there being purely motor convulsive attacks which are independent of any psychical factor and in which all that happens is that the mass of excitation accumulated by summation is discharged, in just the same way as the mass of stimuli caused by anatomical modifications is discharged in an epileptic fit. Here we should have the non-ideogenic hysterical convulsion.[1]

We so often find adolescents who had previously been healthy, though excitable, falling ill of hysteria during pubertal development, that we must ask ourselves whether that process may not create the disposition to hysteria where it was not present innately. And in any case we must attribute more to it than a simple raising of the quantity of excitation. Sexual maturation impinges on the whole nervous system, increasing

1 [Freud (1928*b*) expressed similar views many years later; cf. *RSE*, **21**, 165 ff.]

excitability and reducing resistances everywhere. We are taught this from the observation of adolescents who are not hysterical and we are thus justified in believing that sexual maturation also establishes the hysterical disposition insofar as it consists precisely in this characteristic of the nervous system. In saying this we are already recognizing sexuality as one of the major components of hysteria. We shall see that the part it plays in it is very much greater still and that it contributes in the most various ways to the constitution of the illness.

If the stigmata spring directly from this innate breeding ground of hysteria and are not of ideogenic origin, it is also impossible to give ideogenesis such a central position in hysteria as is sometimes done nowadays. What could be more genuinely hysterical than the stigmata? They are pathognomonic findings which establish the diagnosis; and yet precisely they seem not to be ideogenic. But if the basis of hysteria is an idiosyncrasy of the whole nervous system, the complex of ideogenic, psychically determined symptoms is erected on it as a building is on its foundations. And it is a building *of several storeys*. Just as it is only possible to understand the structure of such a building if we distinguish the plans of the different floors, it is, I think, necessary in order to
[245] understand hysteria for us to pay attention to the various kinds of complication in the causation of the symptoms. If we disregard them and try to carry through an explanation of hysteria by employing a single causal nexus, we shall always find a very large residue of unexplained phenomena left over. It is just as though we tried to insert the different rooms of a many-storeyed house into the plan of a single storey.

Like the stigmata, a number of other nervous symptoms – some pains and vasomotor phenomena and perhaps purely motor convulsive attacks – are, as we have seen, not caused by ideas but are direct results of the fundamental abnormality of the nervous system.

Closest to them are the ideogenic phenomena which are simply conversions of affective excitation (p. 181 above). They arise as the consequences of affects in people with a hysterical disposition and in the first instance they are only an 'abnormal expression of the emotions' (Oppenheim [1890]).[1] This becomes by repetition a genuine and apparently purely somatic hysterical symptom, while the idea that gave rise to it becomes unnoticeable (p. 184) or is fended off and therefore repressed

1 This disposition is nothing else than what Strümpell [1892] speaks of as the 'disturbance in the psychophysical sphere' which underlies hysteria.

from consciousness. The most numerous and important of the ideas that are fended off and converted have a sexual content. They are at the bottom of a great deal of the hysteria of puberty. Girls who are approaching maturity – and it is they who are chiefly concerned – behave very differently towards the sexual ideas and feelings which crowd in on them. Some girls meet them with complete unembarrassment, among whom a few ignore and overlook the whole subject. Others accept them like boys, and this is no doubt the rule with peasant and working-class girls. Others again, with more or less perverse curiosity, run after anything sexual that they can get hold of in talk or books. And lastly there are natures of a refined organization who, though their sexual excitability is great, have an equally great moral purity and who feel that anything sexual is something incompatible with their ethical standards, something dirtying and smirching.[1] They repress sexuality from their consciousness, and the affective ideas with a content of this kind which have caused the somatic phenomena are fended off and thus become unconscious. [246]

The tendency towards fending off what is sexual is further intensified by the fact that in young unmarried women sensual excitation has an admixture of anxiety, of fear of what is coming, what is unknown and half suspected, whereas in normal and healthy young men it is an unmixed aggressive drive. The girl senses in Eros the terrible power which governs and decides her destiny and she is frightened by it. All the greater, then, is her inclination to look away and to repress from her consciousness the thing that frightens her.

Marriage brings fresh sexual traumas. It is surprising that the wedding night does not have pathogenic effects more frequently, since unfortunately what it involves is so often not an erotic seduction but a violation. But indeed it is not rare to find in young married women hysterias which can be traced back to this and which vanish if in the course of time sexual enjoyment emerges and wipes out the trauma. Sexual traumas also occur in the later course of many marriages. The case histories from whose publication we have been obliged to refrain include a great number of them – perverse demands made by the husband, unnatural practices, etc. I do not think I am exaggerating when I assert that *the great majority of severe neuroses in women have their origin in the marriage bed*.[2]

1 Some observations lead us to believe that the fear of touching, or, more properly, the fear of being dirtied, which compels women to keep on washing their hands all the time, very often has this derivation. Their washing is derived from the same mental process as Lady Macbeth's.

2 It is a most unfortunate thing that clinical medicine ignores one of the most important of all the pathogenic factors or at least only hints at it delicately. This is certainly a subject in which the acquired knowledge of experienced physicians should be communicated to their juniors, who as

Certain sexual noxae, which consist essentially in insufficient satisfaction (*coitus interruptus*, *ejaculatio praecox*, etc.), result according to the discovery of Freud (1895*b*) not in hysteria but in an anxiety neurosis. I am of the opinion, however, that even in such cases the excitation of the sexual affect is quite frequently converted into hysterical somatic phenomena.

It is self-evident and is also sufficiently proved by our observations that the nonsexual affects of fright, anxiety and anger lead to the development of hysterical phenomena. But it is perhaps worthwhile insisting
[247] again and again that the sexual factor is by far the most important and the most productive of pathological results. The unsophisticated observations of our predecessors, the residue of which is preserved in the term 'hysteria' [derived from the Greek word for 'uterus'], came nearer the truth than the more recent view which puts sexuality almost last, in order to save the patients from moral reproaches. The sexual needs of hysterical patients are no doubt just as variable in degree from individual to individual as in healthy people and are no stronger than in them; but the former fall ill from them, and, for the most part, precisely owing to struggling against them, owing to their *defence* against sexuality.

Alongside sexual hysteria we must at this point recall hysteria due to fright – traumatic hysteria proper – which constitutes one of the best-known and recognized forms of hysteria.

In what may be called the same stratum as the phenomena which arise from the conversion of affective excitation are to be found those which owe their origin to suggestion (mostly autosuggestion) in individuals who are innately suggestible. A high degree of suggestibility – that is to say, the unrestricted preponderance of ideas that have been freshly aroused – is not among the essential features of hysteria. It can, however, be present as a complication in people with a hysterical disposition, in whom this very idiosyncrasy of the nervous system makes possible the somatic realization of supervalent[1] ideas. Moreover, it is for the most part only *affective* ideas which are realized in somatic phenomena by suggestion, and consequently the process may often be regarded as a conversion of the accompanying affect of fright or anxiety.

These processes – the conversion of affect, and suggestion – remain identical even in the complicated forms of hysteria which we must now

a rule blindly overlook sexuality – at all events so far as their patients are concerned. [Cf. pp. 296 and 305 below.]

1 ['*Überwertig*.' Freud attributes this term to Wernicke in his analysis of 'Dora' (1905*e*), *RSE*, 7, 49. Cf. Wernicke (1900, 140).]

consider. They merely find more favourable conditions in such cases: it is invariably through one of these two processes that psychically determined hysterical phenomena come into being.

The third constituent of the hysterical disposition, which appears in some cases in addition to those that have been already discussed, is the hypnoid state, the tendency to autohypnosis (p. 191 f. above). This state favours and facilitates in the greatest degree both conversion and suggestion; and in this way it erects, as we might say, on the top of the minor hysterias, the higher storey of major hysteria. The tendency to autohypnosis is a state which is to begin with only temporary and which alternates with the normal one. We may attribute to it the same increase of mental influence on the body that we observe in artificial hypnosis. This influence is all the more intense and deep-going here in that it is acting upon a nervous system which even outside hypnosis is abnormally excitable.[1] We cannot tell how far and in what cases the tendency to autohypnosis is an innate property of the organism. I have expressed the view above (pp. 194–5) that it develops from reveries that are charged with affect. But there can be no doubt that innate disposition plays a part in this as well. If this view is correct, it will be clear here once again how great an influence on the development of hysteria is to be ascribed to sexuality. For, apart from sick-nursing, no psychical factor is so well calculated to produce reveries charged with affect as are the longings of a person in love. And over and above this the sexual orgasm[2] itself, with its wealth of affect and its restriction of consciousness, is closely akin to hypnoid states. [248]

The hypnoid element is most clearly manifested in hysterical attacks and in those states which can be described as acute hysteria and which, it seems, play such an important part in the development of hysteria (p. 210 above). These are obviously psychotic states which persist for a long time, often for several months and which it is frequently necessary to describe as hallucinatory confusion. Even if the disturbance does not go as far as this, a great variety of hysterical phenomena emerge in it, a few of which actually persist after it is over. The psychical content of these

1 It is tempting to identify the disposition to hypnosis with innate abnormal excitability; for artificial hypnosis, too, exhibits ideogenic changes in secretion and local blood supply, formation of vesicles, etc. This seems to be the view held by Moebius. But in my opinion it would involve us in a vicious circle. The miraculous workings of hypnosis are, so far as I can see, only observable in hysterical patients. What we should be doing would be first to assign the phenomena of hysteria to hypnosis, and then to assert that hypnosis is the cause of those phenomena.

2 ['*Orgasmus*.' In the first edition only this is misprinted '*Organismus*'.]

states consists partly in precisely the ideas which have been fended off in
[249] waking life and repressed from consciousness. (Cf. the 'hysterical deliria in saints and nuns, continent women and well-brought-up children' [p. 10 above].)

Since these states are so often nothing less than psychoses and are yet derived immediately and exclusively from hysteria, I cannot agree with Moebius's opinion that 'apart from the deliria attached to attacks, it is impossible to speak of an actual hysterical insanity' (1895, 18). In many cases these states constitute an insanity of this kind; and psychoses like these also recur in the further course of a hysteria. It is true that essentially they are nothing other than the psychotic stage of an attack, but since they last for months they can nevertheless hardly be described as attacks.

How does one of these acute hysterias arise? In the best-known case (Case History 1) it developed out of an accumulation of hypnoid attacks; in another case (where there was already a complicated hysteria present) it arose in association with a withdrawal of morphine. The process is for the most part completely obscure and awaits clarification from further observations.

Accordingly, we may apply to the hysterias which have been discussed here Moebius's pronouncement (1895, 16): 'The essential change that occurs in hysteria is that the mental state of the hysterical patient becomes temporarily or permanently similar to that of a hypnotized subject.'

The persistence in the normal state of the symptoms that have arisen during the hypnoid one corresponds entirely to our experiences with post-hypnotic suggestion. But this already implies that complexes of ideas that are inadmissible to consciousness coexist with the trains of ideas that pursue a conscious course, that the splitting of the mind has taken place (p. 204). It seems certain that this can happen even without a hypnoid state, from the wealth of thoughts which have been fended off and repressed from consciousness but not suppressed. In one way or another there comes into existence a region of mental life – sometimes poor in ideas and rudimentary, sometimes more or less on a par with waking thought – our knowledge of which we owe, above all, to Binet and Janet. The splitting of the mind is the consummation of hysteria. I have shown above (in Section 5) how it explains the principal characteristics of the disorder. One part of the patient's mind is in the hypnoid
[250] state, permanently, but with a varying degree of vividness in its ideas, and is always prepared whenever there is a lapse in waking thought to assume control over the whole person (e.g. in an attack or delirium). This occurs

as soon as a powerful affect interrupts the normal course of ideas, in twilight states and states of exhaustion. Out of this persisting hypnoid state unmotivated ideas, alien to normal association, force their way into consciousness, hallucinations are introduced into the perceptual system and motor acts are innervated independently of the conscious will. This hypnoid mind is in the highest degree susceptible to conversion of affects and to suggestion, and thus fresh hysterical phenomena appear easily, which without the split in the mind would only have come about with great difficulty and under the pressure of repeated affects. The split-off mind is the devil with which the unsophisticated observation of early superstitious times believed that these patients were possessed.[1] It is true that a spirit alien to the patient's waking consciousness holds sway in him; but the spirit is not in fact an alien one, but a part of his own.

The attempt that has been made here to make a synthetic construction of hysteria out of what we know of it today is open to the reproach of eclecticism, if such a reproach can be justified at all. There were so many formulations of hysteria, from the old 'reflex theory' to the 'dissociation of personality', which have had to find a place in it. But it can scarcely be otherwise; for so many excellent observers and acute minds have concerned themselves with hysteria. It is unlikely that any of their formulations was without a portion of the truth. A future exposition of the true state of affairs will certainly include them all and will merely combine all the one-sided views of the subject into a corporate reality. Eclecticism, therefore, seems to me nothing to be ashamed of.

But how far we still are today from the possibility of any such complete understanding of hysteria! With what uncertain strokes have its outlines been drawn in these pages, with what clumsy hypotheses have the gaping lacunas been concealed rather than bridged! Only one consideration is to some extent consoling: that this defect attaches, and must attach, to all physiological expositions of complicated psychical processes. We must always say of them what Theseus in *A Midsummer Night's Dream* says of tragedy: 'The best in this kind are but shadows.' And even the weakest is [251] not without value if it honestly and modestly tries to hold on to the outlines of the shadows which the unknown real objects throw upon the wall. For then, in spite of everything, the hope is always justified that there may be some degree of correspondence and similarity between the real processes and our idea of them.[2]

IV

THE PSYCHOTHERAPY OF HYSTERIA

(FREUD)

IV

THE PSYCHOTHERAPY OF HYSTERIA

(FREUD)

In our 'Preliminary Communication' we reported how, in the course of [255]
our investigation into the aetiology of hysterical symptoms, we also came upon a therapeutic method which seemed to us of practical importance. For 'we found, to our great surprise at first, that *each individual hysterical symptom immediately and permanently disappeared when we had succeeded in bringing clearly to light the memory of the event by which it was provoked and in arousing its accompanying affect, and when the patient had described that event in the greatest possible detail and had put the affect into words*'. (p. 6.)

We further endeavoured to explain the way in which our psychotherapeutic method works. '*It brings to an end the operative force of the idea which was not abreacted in the first instance, by allowing its strangulated affect to find a way out through speech; and it subjects it to associative correction by introducing it into normal consciousness (under light hypnosis) or by removing it through the physician's suggestion, as is done in somnambulism accompanied by amnesia.*' (p. 15.)

I will now try to give a connected account of how far this method carries us, of the respects in which it achieves more than other methods, of the technique by which it works and of the difficulties it meets with. Much of the substance of this is already contained in the case histories printed in the earlier portion of this book, and I shall not be able to avoid repeating myself in the account which follows.

(1)

For my own part, I too may say that I can still hold by what is contained in the 'Preliminary Communication'. Nonetheless I must confess that during the years which have since passed – in which I have been unceasingly concerned with the problems touched upon in it – fresh points of view have forced themselves on my mind. These have led to what is in part at least a different grouping and interpretation of the factual [256]

material known to me at that time. It would be unfair if I were to try to lay too much of the responsibility for this development upon my honoured friend Dr Josef Breuer. For this reason the considerations which follow stand principally under my own name.

When I attempted to apply to a comparatively large number of patients Breuer's method of treating hysterical symptoms by an investigation and abreaction of them under hypnosis, I came up against two difficulties, in the course of dealing with which I was led to an alteration both in my technique and in my view [*Auffassung*] of the facts. (1) I found that not everyone could be hypnotized who exhibited undoubted hysterical symptoms and who, it was highly probable, was governed by the same psychical mechanism. (2) I was forced to take up a position on the question of what, after all, essentially characterizes hysteria and what distinguishes it from other neuroses.

I will put off until later my account of how I got over the first of these two difficulties and what I have learnt from it, and I will begin by describing the attitude I adopted in my daily practice towards the second problem. It is very hard to obtain a clear view of a case of neurosis before one has submitted it to a thorough analysis – an analysis which can, in fact, only be brought about by the use of Breuer's method; but a decision on the diagnosis and the form of therapy to be adopted has to be made before any such thorough knowledge of the case has been arrived at. The only course open to me, therefore, was to select for cathartic treatment such cases as could be provisionally diagnosed as hysteria, which exhibited one or more of the stigmata or characteristic symptoms of hysteria. It then sometimes happened that in spite of the diagnosis of hysteria the therapeutic results turned out to be very scanty and that even analysis brought nothing significant to light. On other occasions again, I tried applying Breuer's method of treatment to neuroses which no-one could have mistaken for hysteria, and I found that in that manner they could be influenced and indeed cleared up. I had this experience, for instance,
Zwang with obsessional ideas [*Zwangsvorstellungen*][T], genuine obsessional ideas of the Westphal type,[1] in cases without a single trait which recalled
[257] hysteria. Consequently, the psychical mechanism revealed by the 'Preliminary Communication' could not be pathognomonic for hysteria. Nor could I resolve, merely for the sake of preserving that mechanism as a criterion of it, to lump all these other neuroses in with hysteria. I eventually found a way out of all these emerging doubts by the plan of

1 [Westphal (1877) had given a detailed descriptive classification of these.]

treating all the other neuroses in question in the same way as hysteria. I determined to investigate their aetiology and the nature of their psychical mechanism in every case and to let the decision as to whether the diagnosis of hysteria was justified depend upon the outcome of that investigation.

Thus, starting out from Breuer's method, I found myself engaged in a consideration of the aetiology and mechanism of the neuroses in general. I was fortunate enough to arrive at some serviceable findings in a relatively short time.[1] In the first place I was obliged to recognize that, insofar as one can speak of determining causes which lead to the *acquisition* of neuroses, their aetiology is to be looked for in *sexual* factors. There followed the discovery that different sexual factors, in the most general sense, produce different pictures of neurotic disorders. And it then became possible, in the degree to which this relation was confirmed, to venture on using aetiology for the purpose of characterizing the neuroses and of making a sharp distinction between the clinical pictures of the various neuroses. Where the aetiological characteristics coincided regularly with the clinical ones, this was of course justified.

In this manner I found that neurasthenia presented a monotonous clinical picture in which, as my analyses showed, a 'psychical mechanism' played no part. There was a sharp distinction between neurasthenia and 'obsessional neurosis' [*Zwangsneurose*], the neurosis of obsessional ideas [258]
[*Zwangsvorstellungen*] proper. In this latter one I was able to recognize a complicated psychical mechanism, an aetiology similar to that of hysteria and an extensive possibility of reducing it by psychotherapy. On the other hand, it seemed to me absolutely necessary to detach from neurasthenia a complex of neurotic symptoms which depend on a quite different and indeed at bottom a *contrary* aetiology. The component symptoms of this complex are united by a characteristic which has already been recognized by Hecker (1893). For they are either symptoms or equivalents and rudiments of *manifestations of anxiety*; and for this reason I have given to this complex which is to be detached from neurasthenia the name of 'anxiety neurosis'. I have maintained [Freud, 1895*b*] that it arises from an

1 [The findings reported in this and the next three paragraphs had already been published by Freud in his first paper on 'The Neuropsychoses of Defence' (1894*a*), *RSE*, **3**, 43 ff., and his first paper on anxiety neurosis (1895*b*), ibid., **3**, 81 ff. – In reading what follows, it should be borne in mind that Freud subsequently separated off a further clinical entity to which he gave the name 'anxiety hysteria' and which, though anxiety was its most obvious feature, had a traceable psychical mechanism parallel to that of conversion hysteria. Freud's first lengthy discussion of anxiety hysteria appeared in the case history of 'Little Hans' (1909*b*), ibid., **10**, 88–90. The distinction between 'anxiety neurosis' and 'anxiety hysteria' is brought out very clearly in the paper on 'wild' psychoanalysis (1910*k*), ibid., **11**, 215–16.]

accumulation of physical tension, which is itself once more of sexual origin. This neurosis, too, has no psychical mechanism, but it invariably influences mental life, so that 'anxious expectation', phobias, hyperaesthesia to pains, etc., are among its regular manifestations. This anxiety neurosis, in my sense of the term, no doubt coincides in part with the neurosis which, under the name of 'hypochondria', finds a place in not a few descriptions alongside hysteria and neurasthenia. But I cannot regard the delimitation of hypochondria in any of the works in question as being the correct one, and the applicability of its name seems to me to be prejudiced by the fixed connection of that term with the symptom of 'fear of illness'.[1]

After I had in this way fixed the simple pictures of neurasthenia, anxiety neurosis and obsessional ideas, I went on to consider the cases of neurosis which are commonly included under the diagnosis of hysteria. I reflected that it was not right to stamp a neurosis as a whole as hysterical because a few hysterical signs were prominent in its complex of symptoms. I could well understand this practice, since after all hysteria is the oldest, best-known and most striking of the neuroses under consideration; but it was an abuse, for it put down to the account of hysteria so [259] many traits of perversion and degeneracy. Whenever a hysterical sign, such as an anaesthesia or a characteristic attack, was found in a complicated case of psychical degeneracy, the whole condition was described as one of 'hysteria', so that it is not surprising that the worst and the most contradictory things were found together under this label. But just as it was certain that *this* diagnosis was incorrect, it was equally certain that we ought also to separate out the various neuroses; and since we were acquainted with neurasthenia, anxiety neurosis, etc., in a pure form, there was no longer any need to overlook them in the combined picture.

The following view, therefore, seemed to be the more probable one. The neuroses which commonly occur are mostly to be described as 'mixed'. Neurasthenia and anxiety neuroses are easily found in pure forms as well, especially in young people. Pure forms of hysteria and obsessional neurosis are rare; as a rule these two neuroses are combined with anxiety neurosis. The reason why mixed neuroses occur so

1 [Cf. above, p. 216. – Freud had already considered the relations between hypochondria, neurasthenia and anxiety neurosis in Part I of his first paper on anxiety neurosis (1895*b*), *RSE*, **3**. Much later, in the course of his closing remarks in a discussion on masturbation (1912*f*), ibid., **12**, he suggested that hypochondria should be regarded, together with neurasthenia and anxiety neurosis, as a third 'actual neurosis' – that is, as having a purely physical aetiology. He took up this idea at much greater length in his paper on narcissism (1914*c*), ibid., **14**, 72 ff. The confusing dichotomy between 'physical' and 'psychical' aetiologies is perhaps less so when Moebius's term 'ideogenic' is used. Cf. Editors' Introduction, p. xxiii above.]

frequently is that their aetiological factors are so often intermixed, sometimes only by chance, sometimes as a result of causal relations between the processes from which the aetiological factors of the neuroses are derived. There is no difficulty in tracing this out and demonstrating it in detail. As regards hysteria, however, it follows that that disorder can scarcely be segregated from the nexus of the sexual neuroses for the purposes of study, that as a rule it represents only a single side, only one aspect, of a complicated case of neurosis, and that it is only in marginal cases that it can be found and treated in isolation. We may perhaps say in a number of instances: *a potiori fit denominatio* [i.e. it has been given its name from its more important feature].

I will now examine the case histories that have been reported here, with a view to seeing whether they speak in favour of my opinion that hysteria is not an independent clinical entity.

Breuer's patient, Anna O., seems to contradict my opinion and to be an example of a pure hysterical disorder. This case, however, which has been so fruitful for our knowledge of hysteria, was not considered at all by its observer from the point of view of a sexual neurosis, and is now quite useless for this purpose. When I began to analyse the second patient, Frau Emmy von N., the expectation of a sexual neurosis being the basis [260] of hysteria was fairly remote from my mind. I had come fresh from the school of Charcot, and I regarded the linking of hysteria with the topic of sexuality as a sort of insult – just as the women patients themselves do. When I go through my notes on this case today there seems to me no doubt at all that it must be looked on as a case of severe anxiety neurosis accompanied by anxious expectation and phobias – an anxiety neurosis which originated from sexual abstinence and had become combined with hysteria. Case 3, that of Miss Lucy R., can perhaps best be described as a marginal case of pure hysteria. It was a short hysteria which ran an episodic course and had an unmistakable sexual aetiology, such as would correspond to an anxiety neurosis. The patient was an overmature girl with a need to be loved, whose affections had been too hastily aroused through a misunderstanding. The anxiety neurosis, however, did not become visible, or it escaped me. Case 4, Katharina, was nothing less than a model of what I have described as 'virginal anxiety'.[1] It was a combination of anxiety neurosis and hysteria. The former created the symptoms, while the latter repeated them and operated with them. Incidentally, it was a case typical of a large number of neuroses in young people that are described as 'hysteria'. Case 5, that of Fräulein Elisabeth

1 [See footnote 1, p. 112 above.]

von R., was once again not investigated as a sexual neurosis. I was only able to express, without confirming it, a suspicion that a spinal neurasthenia may have been its basis [p. 155, footnote above].

I must add, though, that in the meantime pure hysterias have become even rarer in my experience. If it was possible for me to bring together these four cases as hysterias and if in reporting them I was able to overlook the points of view that were of importance as regards sexual neuroses, the reason is that these histories date some distance back, and that I did not at that time as yet submit such cases to a deliberate and searching investigation of their neurotic sexual foundation. And if, instead of these four, I did not report *twelve* cases whose analysis provides a confirmation of the psychical mechanism of hysterical phenomena put forward by us, this reticence was necessitated by the very circumstance that the analysis revealed these cases as being simultaneously sexual neuroses, although certainly no diagnostician would have refused them the name
[261] of hysteria. But an elucidation of these sexual neuroses would overstep the bounds of the present joint publication.

I should not like it to be wrongly thought that I do not wish to allow that hysteria is an independent neurotic affection, that I regard it merely as a psychical manifestation of anxiety neurosis and that I attribute to it 'ideogenic' symptoms only and am transferring the somatic symptoms (such as hysterogenic points and anaesthesias) to anxiety neurosis. Nothing of the sort. In my opinion it is possible to deal with hysteria, freed from any admixture, as something independent; and to do so in every respect except in that of therapeutics. For in therapeutics we are concerned with a practical aim, with getting rid of the pathological state as a whole. And if hysteria generally appears as a component of a mixed neurosis, the situation resembles that in which there is a mixed infection, where preserving life sets a problem which does not coincide with that of combating the operation of one particular pathogenic agent.

It is very important for me to distinguish the part played by hysteria in the picture of the mixed neuroses from that played by neurasthenia, anxiety neurosis and so on, because, once I have made this distinction, I shall be able to express concisely the therapeutic value of the cathartic method. For I am inclined to venture the assertion that that method is – as a matter of theory – very well able to get rid of any hysterical symptom, whereas, as will be easily understood, it is completely powerless against the phenomena of neurasthenia and is only able rarely and in roundabout ways to influence the psychical effects of anxiety neurosis. Its therapeutic effectiveness in any particular case will accordingly

depend on whether the hysterical components of the clinical picture do or do not assume a position of practical importance in comparison with the other neurotic components.

There is another obstacle in the way of the effectiveness of the cathartic method, which we have already indicated in the 'Preliminary Communication' [p. 15 f. above]. It cannot affect the underlying causes of hysteria: thus it cannot prevent fresh symptoms from taking the place of the ones which had been got rid of. On the whole, then, I must claim a prominent place for our therapeutic method as employed within the framework of a therapy of the neuroses; but I should like to advise against assessing its value or applying it outside this framework. Since, however, I cannot in these pages offer a 'therapy of the neuroses' of the [262]
sort needed by practitioners, what I have just said is equivalent to postponing my account of the subject to a possible later publication. But I am able, I think, to add the following remarks by way of expansion and elucidation.

(1) I do not maintain that I have actually got rid of all the hysterical symptoms that I have undertaken to influence by the cathartic method. But it is my opinion that the obstacles have lain in the personal circumstances of the patients and have not been due to any question of theory. I am justified in leaving these unsuccessful cases out of account in arriving at a judgement, just as a surgeon disregards cases of death which occur under anaesthesia, owing to post-operational haemorrhage, accidental sepsis, etc., in making a decision about a new technique. When I come to deal with the difficulties and drawbacks of the procedure later on, I shall return to a consideration of failures from this source. [See p. 268 below.]

(2) The cathartic method is not to be regarded as worthless because it is a symptomatic and not a causal one. For a causal therapy is in fact as a rule only a prophylactic one; it brings to a halt any further effects of the noxious agency, but does not therefore necessarily get rid of the results which that agency has already brought about. As a rule a second phase of treatment is required to perform this latter task, and in cases of hysteria the cathartic method is quite invaluable for this purpose.

(3) Where a period of hysterical production, an acute hysterical paroxysm, has been overcome and all that is left over are hysterical symptoms in the shape of residual phenomena, the cathartic method suffices for every indication and brings about complete and permanent successes. A favourable therapeutic constellation of this kind is not seldom to be found precisely in the region of sexual life [*Geschlechtslebens*][T], *Geschlecht*
owing to the wide oscillations in the intensity of sexual needs and the

complications of the conditions necessary in order to bring about a sexual trauma. Here the cathartic method does all that can be asked of it, for the physician cannot set himself the task of altering a constitution such as the hysterical one. He must content himself with getting rid of the troubles to which such a constitution is inclined and which may arise from it with the conjunction of external circumstances. He will feel
[263] satisfied if the patient regains her working capacity. Moreover, he is not without consolation for the future when he considers the possibility of a relapse. He is aware of the principal feature in the aetiology of the neuroses – that their genesis is as a rule *overdetermined*,[1] that several factors must come together to produce this result; and he may hope that this convergence will not be repeated at once, even though a few individual aetiological factors remain operative.

It might be objected that, in cases of hysteria like this, in which the illness has run its course, the residual symptoms in any case pass away spontaneously. It may be said in reply, however, that a spontaneous cure of this kind is very often neither rapid nor complete enough and that it can be assisted to an extraordinary degree by our therapeutic intervention. We may readily leave it for the moment as an unresolved question whether by means of the cathartic therapy we cure only what is capable of spontaneous cure or sometimes also what would not have been cleared up spontaneously.

(4) Where we meet with an acute hysteria, a case which is passing through the period of the most active production of hysterical symptoms and in which the ego [*Ich*] is being constantly overwhelmed[2] by the products of the illness (i.e. during a hysterical psychosis), even the cathartic method will make little change in the appearance and course of the disorder. In such circumstances we find ourselves in the same position as regards the neurosis as a physician faced with an acute infectious disease. The aetiological factors have performed their work sufficiently at a time which has now passed and is beyond the reach of any influence; and now, after the period of incubation has elapsed, they have become manifest. The illness cannot be broken off short. We must wait for it to run its course and in the meantime make the patient's circumstances as favourable as possible.[3] If, during an acute period like this, we get rid of the products of the illness, the freshly generated hysterical symptoms, we

1 [See footnote 1, p. 189 above.]

2 [Cf. *RSE*, **1**, 254–5.]

3 [*günstigsten*. In the German original this word was *günstigen* ('favourable'); it was corrected in the *GW*, making the sense 'as favourable as possible'.]

must also be prepared to find that those that have been got rid of will promptly be replaced by others. The physician will not be spared the depressing feeling of being faced with a Sisyphean task. The immense expenditure of labour, and the dissatisfaction of the patient's family, to whom the inevitable length of an acute neurosis is not likely to be as familiar as the analogous case of an acute infectious disease – these and [264] other difficulties will probably make a systematic application of the cathartic method as a rule impossible in any given case. Nevertheless, it remains a matter for serious consideration whether it may not be true that even in an acute hysteria the regular clearing up of the products of the illness exercises a curative influence, by supporting the patient's normal ego which is engaged in the work of defence, and by preserving it from being overwhelmed and falling into a psychosis and even perhaps into a permanent state of confusion.

What the cathartic method is able to accomplish even in acute hysteria, and how it even restricts the fresh production of pathological symptoms in a manner that is of practical importance, is quite clearly revealed by the case history of Anna O., in which Breuer first learnt to employ this psychotherapeutic procedure.

(5) Where it is a question of hysterias which run a chronic course, accompanied by a moderate but constant production of hysterical symptoms, we find the strongest reason for regretting our lack of a therapy which is effective causally, but we also have most ground for the appreciation of the value of the cathartic procedure as a *symptomatic* therapy. In such cases we have to do with the mischief produced by an aetiology that persists chronically. Everything depends on reinforcing the patient's nervous system in its capacity to resist; and we must reflect that the existence of a hysterical symptom means a weakening of the resistance of that nervous system and represents a factor predisposing to hysteria. As can be seen from the mechanism of monosymptomatic hysteria, a new hysterical symptom is most easily formed in connection with, and on the analogy of, one that is already present. The point at which a symptom has already broken through once (see p. 181) forms a weak spot at which it will break through again the next time. A psychical group that has once been split off plays the part of a 'provoking' crystal from which a crystallization which would otherwise not have occurred will start with the greatest facility [p. 108]. To get rid of the symptoms which are already present, to undo the psychical changes which underlie them, is to give back to patients the whole amount of their capacity for resistance, so that they can successfully withstand the effects of the noxious agency. A very

[265] great deal can be done for such patients by means of prolonged supervision and occasional 'chimney-sweeping' (p. 27).

(6) It remains for me to mention the apparent contradiction between the admission that not all hysterical symptoms are psychogenic and the assertion that they can all be got rid of by a psychotherapeutic procedure. The solution lies in the fact that some of these non-psychogenic symptoms (stigmata, for instance) are, it is true, indications of illness, but cannot be described as ailments; and consequently it is not of practical importance if they persist after the successful treatment of the illness. As regards other such symptoms, it seems to be the case that in some roundabout way they are carried off along with the psychogenic symptoms, just as, perhaps, in some roundabout way they are after all dependent on a psychical causation.

I must now consider the difficulties and disadvantages of our therapeutic procedure, so far as they do not become obvious to everyone from the case histories reported above or from the remarks on the technique of the method which follow later. I will enumerate and indicate these difficulties rather than elaborate them.

The procedure is laborious and time-consuming for the physician. It presupposes great interest in psychological happenings, but personal concern for the patients as well. I cannot imagine bringing myself to delve into the psychical mechanism of a hysteria in anyone who struck me as low-minded and repellent, and who, on closer acquaintance, would not be capable of arousing human sympathy; whereas I can keep the treatment of a tabetic or rheumatic patient apart from personal approval of this kind. The demands made on the patient are not less. The procedure is not applicable at all below a certain level of intelligence, and it is made very much more difficult by any trace of feebleness of mind. The complete consent and complete attention of the patients are needed, but above all their confidence, since the analysis invariably leads to the disclosure of the most intimate and secret psychical events. A good number of the patients who would be suitable for this form of treatment abandon the doctor as soon as the suspicion begins to dawn on them of the direction in which the investigation is leading. For patients such as
[266] these the doctor has remained a stranger. With others, who have decided to put themselves in his hands and place their confidence in him – a step which in other such situations is only taken voluntarily and never at the doctor's request – with these other patients, I say, it is almost inevitable that their personal relation to him will force itself, for a time at least,

unduly into the foreground. It seems, indeed, as though an influence of this kind on the part of the doctor is a *sine qua non* to a solution to the problem.[1] I do not think any essential difference is made in this respect whether hypnosis can be used or whether it has to be bypassed and replaced by something else. But reason demands that we should emphasize the fact that these drawbacks, though they are inseparable from our procedure, cannot be laid at its door. On the contrary, it is quite clear that they are based on the predetermining conditions of the neuroses that are to be cured and that they must attach to any medical activity which involves intense preoccupation with the patient and leads to a psychical change in him. I have not been able to attribute any deleterious effects or danger to the employment of hypnosis, though I made copious use of it in some of my cases. Where I caused damage, the reasons lay elsewhere and deeper. If I survey my therapeutic efforts during the last few years since the communications made by my honoured teacher and friend Josef Breuer showed me the use of the cathartic method, I believe that in spite of everything, I have done much more, and more frequent, good than harm and have accomplished some things which no other therapeutic procedure could have achieved. It has on the whole, as the 'Preliminary Communication' put it, brought 'considerable therapeutic advantages' [p. 15 above].

There is one other advantage in the use of this procedure which I must emphasize. I know of no better way of getting to understand a severe case of complicated neurosis with a greater or lesser admixture of hysteria than by submitting it to an analysis by Breuer's method. The first thing that happens is the disappearance of whatever exhibits a hysterical mechanism. In the meantime I have learnt in the course of the analysis to interpret the residual phenomena and to trace their aetiology; and in this way I have secured a firm basis for deciding which of the weapons in the therapeutic armoury against the neuroses is indicated in the case concerned. When I reflect on the difference that I usually find between [267]
my judgement on a case of neurosis *before* and *after* an analysis of this kind, I am almost inclined to regard an analysis as essential for the understanding of a neurotic illness. Moreover, I have adopted the habit of combining cathartic psychotherapy with a rest cure which can, if need be, be extended into a complete treatment of feeding-up on Weir Mitchell lines. This gives me the advantage of being able on the one hand to avoid the very disturbing introduction of new psychical impressions during a psychotherapy, and on the other hand to remove the boredom

1 [This topic is discussed at greater length below, p. 268 ff.]

of a rest cure, in which the patients not infrequently fall into the habit of harmful daydreaming. It might be expected that the often very considerable psychical work imposed on the patients during a cathartic treatment, and the excitations resulting from the reproduction of traumatic experiences, would run counter to the intentions of the Weir Mitchell rest cure and would hinder the successes which we are accustomed to see it bring about. But the opposite is in fact the case. A combination such as this between the Breuer and Weir Mitchell procedures produces all the physical improvement that we expect from the latter, as well as having a far-reaching psychical influence such as never results from a rest cure without psychotherapy.[1]

(2)

I will now return to my earlier remark [p. 228 above] that in my attempts to apply Breuer's method more extensively I came upon the difficulty that a number of patients could not be hypnotized, although their diagnosis was one of hysteria and it seemed probable that the psychical mechanism described by us operated in them. I needed hypnosis to extend their memory in order to find the pathogenic recollections which were not present in their ordinary consciousness. I was obliged therefore either to give up the idea of treating such patients or to endeavour to bring about this extension in some other way.

I was able as little as anyone else to explain why it is that one person
[268] can be hypnotized and another not, and thus I could not adopt a causal method of meeting the difficulty. I noticed, however, that in some patients the obstacle lay still further back: they refused even any *attempt* at hypnosis. The idea then occurred to me one day that the two cases might be identical and that both might signify an unwillingness; that people who were not hypnotizable were people who had a psychical objection to hypnosis, whether their objection was expressed as unwillingness or not. I am not clear in my mind whether I can maintain this view.

The problem was, however, how to bypass hypnosis and yet obtain the pathogenic recollections. This I succeeded in doing in the following manner.

When, at our first interview, I asked my patients if they remembered what had originally occasioned the symptom concerned, in some cases they said they knew nothing of it, while in others they brought forward

1 [Weir Mitchell's book on *The Treatment of Certain Forms of Neurasthenia and Hysteria* had been favourably reviewed by Freud (1887*b*).]

something which they described as an obscure recollection and could not pursue further. If, following the example of Bernheim when he awoke in his patients impressions from their somnambulistic state which had ostensibly been forgotten (cf. p. 97), I now became insistent – if I assured them that they *did* know it, that it would occur to their minds – then, in the first cases, something did actually occur to them [*fiel . . . ein*][T], and, *Einfall* in the others, their memory went a step further. After this I became still more insistent; I told the patients to lie down and deliberately close their eyes in order to 'concentrate' – all of which had at least some resemblance to hypnosis. I then found that without any hypnosis new recollections emerged which went further back and which probably related to our topic. Experiences like this made me think that it would in fact be possible for the pathogenic groups of ideas [*Vorstellungsreihen*], that were after all certainly present, to be brought to light by mere insistence; and since this insistence involved effort on my part and so suggested the idea [*Deutung*] that I had to overcome a resistance, the situation led me at once to the theory that *by means of my psychical work I had to overcome a psychical force* [*Kraft*][T] *in the patients which was opposed to the pathogenic ideas becoming conscious (being remembered)*. A new understanding seemed to open before my eyes when it occurred to me that this must no doubt be the same psychical force that had played a part in the generating of the hysterical symptom and had at that time prevented the pathogenic idea from becoming conscious. What kind of [269] force could one suppose was operative here, and what motive could have put it into operation? I could easily form an opinion on this. For I already had at my disposal a few completed analyses in which I had come to know examples of ideas that were pathogenic, and had been forgotten and put out of consciousness. From these I recognized a universal characteristic of such ideas: they were all of a distressing nature, calculated to arouse the affects of shame, of self-reproach and of psychical pain, and the feeling of being harmed; they were all of a kind that one would prefer not to have experienced, that one would rather forget. From all this there arose, as it were automatically, the thought of *defence* [*Abwehr*]. It has indeed been generally admitted by psychologists that the acceptance of a new idea (acceptance in the sense of believing or of recognizing as real) is dependent on the nature and trend of the ideas already united in the ego, and they have invented special technical names for this process of censorship[1] to which the new arrival must submit. The patient's ego had been approached by an idea which proved to be incompatible

1 [*zensur.* This appears to be Freud's first published use of the term.]

[*unverträglich*], which provoked on the part of the ego a repelling force of which the purpose was defence against this incompatible idea. This defence was in fact successful. The idea in question was forced out of consciousness and out of memory. The psychical trace of it was apparently lost to view. Nevertheless, that trace must be there. If I endeavoured to direct the patient's attention to it, I became aware, in the form of *resistance* [*Widerstand*], of the same force as had shown itself in the form of *repulsion* [*Abstossung*] when the symptom was generated. If, now, I could make it appear probable that the idea had become pathogenic precisely as a result of its expulsion and repression [*Verdrängung*], the chain would seem complete. In several of the discussions on our case histories, and in a short paper on 'The Neuropsychoses of Defence' (1894*a*), I have attempted to sketch out the psychological hypotheses by the help of which this causal connection – the fact of conversion – can be demonstrated.

Thus a psychical force, aversion on the part of the ego, had originally driven the pathogenic idea out of association and was now[1] opposing its
[270] return to memory. The hysterical patient's 'not knowing' was in fact a 'not wanting to know' – a not wanting which might be to a greater or lesser extent conscious. The task of the therapist, therefore, lies in overcoming by his psychical work this resistance to association. He does this in the first place by 'insisting' ['*Drängen*'][t], by making use of psychical compulsion [*Zwanges*] to direct the patients' attention to the ideational traces of which he is in search. His efforts, however, are not exhausted by this, but, as I shall show, they take on other forms in the course of an analysis and call in other psychical forces to assist them.

I must dwell on the question of insistence a little longer. Simple assurances such as 'of course you know it', 'tell me all the same', 'you'll think of it in a moment' do not carry us very far. Even with patients in a state of 'concentration' the thread breaks off after a few sentences. It should not be forgotten, however, that it is always a question here of a *quantitative* comparison, of a struggle between motive forces [*motiven*][T] of different degrees of strength or intensity. Insistence on the part of a strange doctor who is unfamiliar with what is happening is not powerful enough to deal with the 'resistance to association' ['*Assoziationswiderstande*'] in a serious case of hysteria. We must think of stronger means.

1 ['*Jetzt*.' This word is found only in the first edition. It is omitted, probably by accident, in all the later editions.]

In these circumstances I make use in the first instance of a small technical device.[1] I inform the patient that, a moment later, I shall apply pressure to his forehead, and I assure him that, all the time the pressure lasts, he will see before him a recollection in the form of a picture or will have it in his thoughts in the form of an idea occurring to him [*als Einfall*]; and I pledge him to communicate this picture or idea to me, whatever it may be. He is not to keep it to himself because he may happen to think it is not what is wanted, not the right thing, or because it would be too disagreeable for him to say it. There is to be no criticism of it, no reticence, either for emotional reasons or because it is judged unimportant. Only in this manner can we find what we are in search of, but in this manner we shall find it infallibly. Having said this, I press for a few seconds on the forehead of the patient as he lies in front of me; I then leave go and ask quietly, as though there were no question of a disappointment: 'What did you see?' or 'What occurred to you?'

This procedure has taught me much and has also invariably achieved its aim. Today I can no longer do without it. I am of course aware that a [271] pressure on the forehead like this could be replaced by any other signal or by some other exercise of physical influence on the patient; but since the patient is lying in front of me, pressure on his forehead, or taking his head between my two hands, seems to be the most convenient way of applying suggestion for the purpose I have in view. It would be possible for me to say by way of explaining the efficacy of this device that it corresponded to a 'momentarily intensified hypnosis'; but the mechanism of hypnosis is so puzzling to me that I would rather not make use of it as an explanation. I am rather of the opinion that the advantage of the procedure lies in the fact that by means of it I dissociate the patient's attention from his conscious searching and reflecting – from everything, in short, on which he can employ his will – in the same sort of way in which this is effected by staring into a crystal ball, and so on.[2] The conclusion which I draw from the fact that what I am looking for always appears under the pressure of my hand is as follows. The pathogenic idea which has ostensibly been forgotten is always lying ready 'close at hand' and can be reached by associations [*Assoziationen*] that are easily accessible. It is merely a question of getting some obstacle out of the way. This obstacle seems once again to be the subject's will, and

1 [See pp. 97–8 and *n*. above.]

2 [The part played in the technique of hypnotism by distracting conscious attention was discussed by Freud much later, in Chapter X of his *Group Psychology* (1921*c*), *RSE*, **18**, 117. Further references to the use of the same mechanism in telepathy and in joking are enumerated in a footnote to that passage. See also ibid., **3**, 186.]

different people can learn with different degrees of ease to free themselves from their intentional thinking and to adopt an attitude of completely objective observation towards the psychical processes taking place in them.[1]

What emerges under the pressure of my hand is not always a 'forgotten' recollection; it is only in the rarest cases that the actual pathogenic recollections lie so easily to hand on the surface. It is much more frequent for an idea to emerge which is an intermediate link in the chain of associations between the idea from which we start and the pathogenic idea which we are in search of; or it may be an idea which forms the starting point of a new series of thoughts and recollections at the end of [272] which the pathogenic idea will be found. It is true that where this happens my pressure has not revealed the pathogenic idea – which would in any case be incomprehensible, torn from its context and without being led up to – but it has pointed the way to it and has shown the direction in which further investigation is to be made. The idea that is first provoked by the pressure may in such cases be a familiar recollection which has never been repressed. If on our way to the pathogenic idea the thread is broken off once more, it only needs a repetition of the procedure, of the pressure, to give us fresh bearings and a fresh starting point.

On yet other occasions the pressure of the hand provokes a memory which is familiar in itself to the patient, but the appearance of which astonishes him because he has forgotten its relation to the idea from which we started. This relation is then confirmed in the further course of the analysis. All these consequences of the pressure give one a deceptive impression of there being a superior intelligence outside the patient's consciousness which keeps a large amount of psychical material arranged for particular purposes and has fixed a planned order for its return to consciousness. I suspect, however, that this unconscious second intelligence is no more than an appearance.

In every fairly complicated analysis the work is carried on by the repeated, indeed continuous, use of this procedure of pressure on the forehead. Sometimes this procedure, starting from where the patient's waking retrospection breaks off, points the further path through memories of which he has remained aware; sometimes it draws attention to connections which have been forgotten; sometimes it calls up and arranges recollections which have been withdrawn from association for many years but which can still be recognized as recollections; and

1 [The difficulty felt by some people in adopting this noncritical attitude was discussed by Freud at some length in Chapter II of *The Interpretation of Dreams* (1900*a*), *RSE*, **4**, 90–2.]

sometimes, finally, as the climax of its achievement in the way of reproductive thinking, it causes thoughts to emerge which the patient will never recognize as his own, which he never *remembers*, although he admits that the context calls for them inexorably, and while he becomes convinced that it is precisely these ideas that are leading to the conclusion of the analysis and the removal of his symptoms.

I will try to enumerate a few instances of the excellent results brought about by this technical procedure.

I treated a girl suffering from an intolerable *tussis nervosa* which had [273] dragged on for six years. It obviously drew nourishment from every common catarrh, but must nevertheless have had strong psychical motives. All other kinds of therapy had long proved impotent against it. I therefore tried to remove the symptom by means of psychical analysis. All she knew was that her nervous cough began when, at the age of fourteen, she was boarding with an aunt. She maintained that she knew nothing of any mental agitations at that time and did not believe that there was any motive for her complaint. Under the pressure of my hand she first of all remembered a big dog. She then recognized the picture in her memory: it was a dog of her aunt's which became attached to her, followed her about everywhere, and so on. And it now occurred to her [*fällt . . . ein*][T], without further prompting, that this dog died, that the *Einfall* children gave it a solemn burial and that her cough started on the way back from the funeral. I asked why, but had once more to call in the help of a pressure. The thought then came to her: 'Now I am quite alone in the world. No-one here loves me. This creature was my only friend, and now I have lost him.' She continued her story. 'The cough disappeared when I left my aunt's, but it came on again eighteen months later.' 'Why was that?' 'I don't know.' I pressed again. She recalled the news of her uncle's death, when the cough started again, and also recalled having a similar train of thought. Her uncle seems to have been the only member of the family who had shown any feeling for her, who had loved her. Here, then, was the pathogenic idea. No-one loved her, they preferred everyone else to her, she did not deserve to be loved, and so on. But there was something attaching to the idea of 'love' which there was a strong resistance to her telling me. The analysis broke off before this was cleared up.

Some time ago I was asked to relieve an elderly lady of her attacks of anxiety, though judging by her traits of character she was scarcely suitable for treatment of this kind. Since her menopause she had become

excessively pious, and she used to receive me at each visit armed with a small ivory crucifix concealed in her hand, as though I were the Evil One. Her anxiety attacks, which were of a hysterical character, went back to her early girlhood and, according to her, originated from the use of a
[274] preparation of iodine intended to reduce a moderate swelling of her thyroid gland. I naturally rejected this derivation and tried to find another instead of it which would harmonize better with my views on the aetiology of the neuroses. I asked her first for an impression from her youth which stood in a causal relation to her anxiety attacks, and, under the pressure of my hand, a memory emerged of her reading what is known as an 'edifying' book, in which there occurred a mention, in a sufficiently pious strain, of the sexual processes. The passage in question made an impression on the girl which was quite the reverse of the author's intention: she burst into tears and flung the book away. This was *before* her first anxiety attack. A second pressure on the patient's forehead conjured up a further reminiscence – the recollection of a tutor of her brothers who had manifested a great admiration for her and towards whom she herself had had feelings of some warmth. This recollection culminated in the reproduction of an evening in her parents' house when they had all sat round the table with the young man and had enjoyed themselves immensely in an entertaining conversation. During the night following that evening she was woken up by her first anxiety attack which, it is safe to say, had more to do with a repudiation of a sensual impulse than with any contemporary doses of iodine. – What prospect should I have had by any other method of revealing such a connection, against her own views and assertions, in this recalcitrant patient who was so prejudiced against me and every form of mundane therapy?

Another example concerns a young, happily married woman. As long ago as in her early girlhood she used for some time to be found every morning in a stuporous condition, with her limbs rigid, her mouth open and her tongue protruding; and now once again she was suffering, on waking, from attacks which were similar though not so severe. Since deep hypnosis turned out not to be obtainable, I began to investigate while she was in a state of concentration. At my first pressure I assured her that she would see something that was directly related to the causes of her condition in her childhood. She was quiet and cooperative. She saw once more the house in which she had spent her early girlhood, her own room, the position of her bed, her grandmother, who had lived with them at that time, and one of her governesses of whom she had been very fond. A number of small scenes, all of them unimportant, which took

place in these rooms and between these people followed one after the other; they were concluded by the departure of the governess, who left in order to get married. I could make nothing at all of these reminiscences; I could not establish any relation between them and the aetiology of the attacks. Various circumstances showed, however, that they belonged to the same period at which the attacks first appeared. But before I was able to proceed with the analysis I had occasion to talk to a colleague who in former years had been the family doctor of my patient's parents. He gave me the following information. At the time at which he was treating the girl, who was approaching maturity and very well developed physically, for her first attacks, he was struck by the excessive affectionateness of the relation between her and the governess who was at that time in the house. He became suspicious and induced the grandmother to keep an eye on this relationship. After a short time the old lady was able to report to him that the governess was in the habit of visiting the child in bed at night and that after such nights the child was invariably found next morning in an attack. They did not hesitate after this to arrange for the silent removal of this corrupter of youth. The children and even the mother were encouraged to believe that the governess had left in order to get married. – My therapy, which was immediately successful, consisted in giving the young woman the information I had received. [275]

The revelations which one obtains through the procedure of pressing occasionally appear in a very remarkable form and in circumstances which make the assumption of there being an unconscious intelligence even more tempting. Thus I remember a lady who had suffered for many years from obsessions and phobias and who referred me to her childhood for the genesis of her illness but was also quite unable to say what might be to blame for it. She was frank and intelligent and she put up only a remarkably small conscious resistance. (I may remark in parenthesis that the psychical mechanism of obsessions has a very great deal of internal kinship with hysterical symptoms and that the technique of analysis is the same for both of them.) When I asked this lady whether she had seen anything or had any recollection under the pressure of my hand, she replied: 'Neither the one nor the other, but a word has suddenly occurred to me.' 'A single word?' 'Yes, but it sounds too silly.' 'Say it all the same.' 'Concierge.' 'Nothing else?' 'No.' I pressed a second time and once more an isolated word shot through her mind: 'Nightgown.' I saw now that this was a new sort of method of answering, and by pressing repeatedly I brought out what seemed to be a meaningless series of [276]

words: 'Concierge' – 'nightgown' – 'bed' – 'town' – 'farm-cart.' 'What does all this mean?' I asked. She reflected for a moment and the following thought occurred to her: 'It must be the story that has just come into my head. When I was ten years old and my next elder sister was twelve, she went raving mad one night and had to be tied down and taken into the town on a farm-cart. I remember perfectly that it was the concierge who overpowered her and afterwards went with her to the asylum as well.' We pursued this method of investigation and our oracle produced another series of words, which, though we were not able to interpret all of them, made it possible to continue this story and lead on from it to another one. Soon, moreover, the meaning of this reminiscence became clear. Her sister's illness had made such a deep impression on her because the two of them shared a secret; they slept in one room and on a particular night they had both been subjected to sexual assaults by a certain man. The mention of this sexual trauma in the patient's childhood revealed not only the origin of her first obsessions but also the trauma which subsequently produced the pathogenic effects.

The peculiarity of this case lay only in the emergence of isolated keywords [*Schlagworten*] which we had to work into sentences; for the appearance of disconnectedness and irrelevance which characterized the words emitted in this oracular fashion applies equally to the complete ideas and scenes which are normally produced under my pressure. When these are followed up, it invariably turns out that the apparently disconnected reminiscences are closely linked in thought and that they lead quite straight to the pathogenic factor we are looking for. For this reason I am glad to recall a case of analysis in which my confidence in the products of pressure were first put to a hard test but afterwards brilliantly justified.

A very intelligent and apparently happy young married woman had consulted me about an obstinate pain in her abdomen which was resistant to treatment. I recognized that the pain was situated in the abdominal
[277] wall and must be referred to palpable muscular indurations, and I ordered local treatment. Some months later I saw the patient again and she said to me: 'The pain I had then passed off after the treatment you recommended, and it stayed away for a long time; but now it has come back in a nervous form. I know that is so, because I no longer have it, as I used to, when I make certain movements, but only at particular times – for instance, when I wake up in the morning and when I am agitated in certain ways.' The lady's diagnosis was quite correct. It was now a question of finding out the cause of the pain, and she could not help me about this

while she was in an uninfluenced state. When I asked her, in concentration and under the pressure of my hand, whether anything occurred to her or whether she saw anything, she decided in favour of seeing and began to describe her visual pictures. She saw something like a sun with rays, which I naturally took to be a phosphene, produced by pressure on the eyes. I expected that something more serviceable would follow. But she went on: 'Stars of a curious pale blue light, like moonlight' and so on, all of which I took to be no more than flickering, flashes and bright specks before her eyes. I was already prepared to regard this experiment as a failure and I was wondering how I could make an inconspicuous retreat from the affair, when my attention was attracted by one of the phenomena which she described. She saw a large black cross, leaning over, which had round its edges the same shimmer of light with which all her other pictures had shone, and on whose crossbeam a small flame flickered. Clearly there could no longer be any question of a phosphene here. I now listened carefully. Quantities of pictures appeared bathed in the same light, curious signs looking rather like Sanskrit; figures like triangles, among them a large triangle; the cross once more. . . . This time I suspected an allegorical meaning and asked what the cross could be. 'It probably means pain,' she replied. I objected that by 'cross' one usually meant a moral burden. What lay concealed behind the pain? She could not say, and went on with her visions: a sun with golden rays. And this she was also able to interpret. 'It's God, the primaeval force.' Then came a gigantic lizard which regarded her enquiringly but not alarmingly. Then a heap of snakes. Then once more a sun, but with mild, silver rays; and in front of her, between her and this source of light, a grating which hid the centre of the sun from her. I had known for some time that what [278]
I had to deal with were allegories and at once asked the meaning of this last picture. She answered without hesitation: 'The sun is perfection, the ideal, and the grating represents my weaknesses and faults which stand between me and the ideal.' 'Are you reproaching yourself, then? Are you dissatisfied with yourself?' 'Yes indeed.' 'Since when?' 'Since I have been a member of the Theosophical Society and have been reading its publications. I always had a low opinion of myself.' 'What has made the strongest impression on you recently?' 'A translation from the Sanskrit which is just now coming out in instalments.' A minute later I was being initiated into her mental struggles and her self-reproaches, and was hearing about a small episode which gave rise to a self-reproach – an occasion on which what had previously been an organic pain now for the first time appeared as the consequence of the conversion of an excitation. The pictures

which I had first taken for phosphenes were symbols of trains of thought influenced by the occult and were perhaps actually emblems from the title pages of occult books.

Hitherto I have been so warm in my praises of the achievements of pressure as an auxiliary procedure, and I have the whole time so greatly neglected the aspect of defence or resistance, that I may no doubt have created an impression that this little device has put us in a position to master the psychical obstacles to a cathartic treatment. But to believe this would be to make a serious mistake. Gains of this kind, so far as I can see, are not to be looked for in treatment. Here, as elsewhere, a large change requires a large amount of work. The procedure by pressure is no more than a trick for temporarily taking unawares an ego which is eager for defence. In all fairly serious cases the ego recalls its aims once more and proceeds with its resistance.

I must mention the different forms in which this resistance appears. One is that, as a rule, the pressure procedure fails on the first or second occasion. The patient then declares, very disappointedly: 'I expected something would occur [*einfallen*] to me, but all I thought was how tensely I was expecting it. Nothing came.' The fact of the patient putting himself on his guard like this does not yet amount to an obstacle. We can say in reply: 'It's precisely because you were too curious; it will work
[279] next time.' And in fact it does work. It is remarkable how often patients, even the most docile and intelligent, can completely forget their undertaking, though they had agreed to it beforehand. They promised to say whatever occurred to them under the pressure of my hand, irrespectively of whether or not it seemed to them relevant, and of whether or not it was agreeable to them to say it – to say it, that is, without selecting and without being influenced by criticism or affect. But they do not keep this promise; it is evidently beyond their strength to do so. The work keeps on coming to a stop and they keep on maintaining that this time nothing has occurred to them. We must not believe what they say, we must always assume, and tell them, too, that they have kept something back because they thought it unimportant or found it distressing. We must insist on this, we must repeat the pressure and represent ourselves as infallible, till at last we are really told something. The patient then adds: 'I could have told you that the first time.' 'Why didn't you say it?' 'I couldn't believe it could be that. It was only when it came back every time that I made up my mind to say it.' Or else: 'I hoped it wouldn't be that of all things. I could well do without saying that. It was only when it refused to be

repressed that I saw I shouldn't be let off.' Thus after the event [*nachträglich*] the patient betrays the motives for a resistance which he refused to admit to begin with. He is evidently quite unable to do anything but put up resistance.

This resistance often conceals itself behind some remarkable excuses. 'My mind is distracted today; the clock (or the piano in the next room) is disturbing me.' I have learnt to answer such remarks: 'Not at all. You have at this moment come up against something that you had rather not say. It won't do any good. Go on thinking about it.' The longer the pause between my hand pressure and the patient's beginning to speak, the more suspicious I become and the more it is to be feared that the patient is rearranging what has occurred to him and is mutilating it in his reproduction of it. A most important piece of information is often announced as being a redundant accessory, like an opera prince disguised as a beggar. 'Something has occurred to me now, but it has nothing to do with the subject. I'm only saying it because you want to know everything.' Accompanying words such as these usually introduce the long-sought solution. I always prick up my ears when I hear a patient speak so disparagingly of something that has occurred to him. For it is an indication that [280] defence has been successful if the pathogenic ideas seem, when they re-emerge, to have so little importance. From this we can infer in what the process of defence consisted: it consisted in turning a strong idea into a weak one, in robbing it of its affect.

A pathogenic recollection is thus recognizable, among other things, by the fact that the patient describes it as unimportant and nevertheless only utters it under resistance. There are cases, too, in which the patient tries to disown it even after its return. 'Something has occurred to me now, but you obviously put it into my head.' Or, 'I know what you expect me to answer. Of course you believe I've thought this or that.' A particularly clever method of disavowal lies in saying: 'Something has occurred to me now, it's true, but it seems to me as if I'd put it in deliberately. It doesn't seem to be a reproduced thought at all.' In all such cases, I remain unshakeably firm. I avoid entering into any of these distinctions but explain to the patient that they are only forms of his resistance and pretexts raised by it against reproducing this particular memory, which we must recognize in spite of all this.

When memories return in the form of pictures our task is in general easier than when they return as thoughts. Hysterical patients, who are as a rule of a 'visual' type, do not make such difficulties for the analyst as those with obsessions.

Once a picture has emerged from the patient's memory, we may hear him say that it becomes fragmentary and obscure in proportion as he proceeds with his description of it. *The patient is, as it were, getting rid of it by turning it into words*. We go on to examine the memory picture itself in order to discover the direction in which our work is to proceed. 'Look at the picture once more. Has it disappeared?' 'Most of it, yes, but I still see this detail.' 'Then this residue must still mean something. Either you will see something new in addition to it, or something will occur to you in connection with it.' When this work has been accomplished, the patient's field of vision is once more free and we can conjure up another picture. On other occasions, however, a picture of this kind will remain obstinately before the patient's inward eye, in spite of his having described it; and this is an indication to me that he still has something
[281] important to tell me about the topic of the picture. As soon as this has been done the picture vanishes, like a ghost that has been laid.

It is of course of great importance for the progress of the analysis that one should always turn out to be in the right *vis-à-vis* the patient, otherwise one would always be dependent on what he chose to tell one. It is therefore consoling to know that the pressure technique in fact never fails, apart from a single case, which I shall have to discuss later [p. 268 ff. below] but of which I can at once say that it corresponds to a particular motive for resistance. It can of course happen that one makes use of the procedure in circumstances in which there is nothing for it to reveal. For instance, we may ask for the further aetiology of a symptom when we already have it completely before us, or we may investigate a psychical genealogy of a symptom, such as a pain, which is in fact a somatic one. In such cases the patient will equally assert that nothing has occurred to him and this time he will be in the right. We can avoid doing the patient an injustice if we make it a quite general rule all through the analysis to keep an eye on his facial expression as he lies quietly before us. We can then learn to distinguish without any difficulty the restful state of mind that accompanies the real absence of a recollection from the tension and signs of emotion with which he tries to disavow the emerging recollection, in obedience to defence. Moreover, experiences like these make it possible also to use the pressure technique for purposes of differential diagnosis.

Thus even with the assistance of the pressure technique the work is by no means easy. The one advantage that we gain is of learning from the results of this procedure the direction in which we have to conduct our enquiries and the things that we have to insist upon to the patient. With

some cases this suffices. The principal point is that I should guess the secret and tell it to the patient straight out; and he is then as a rule obliged to abandon his rejection of it. In other cases more is required. The patient's persisting resistance is indicated by the fact that connections are broken, solutions fail to appear, the pictures are recalled indistinctly and incompletely. Looking back from a later period of an analysis to an earlier one, we are often astonished to realize in what a mutilated manner all the ideas and scenes emerged which we extracted from the patient by the procedure of pressing. Precisely the essential elements of the pic- [282]
ture were missing – its relation to himself or to the main contents of his thoughts – and that is why it remained unintelligible.

I will give one or two examples of the way in which a censoring of this kind operates when pathogenic recollections first emerge. For instance, the patient sees the upper part of a woman's body with the dress not properly fastened – out of carelessness, it seems. It is not until much later that he fits a head to this torso and thus reveals a particular person and his relation to her. Or he brings up a reminiscence from his childhood of two boys. What they look like is quite obscure to him, but they are said to have been guilty of some misdeed. It is not until many months later and after the analysis has made great advances that he sees this reminiscence once more and recognizes himself in one of the children and his brother in the other.

What means have we at our disposal for overcoming this continual resistance? Few, but they include almost all those by which one man can ordinarily exert a psychical influence on another. In the first place, we must reflect that a psychical resistance, especially one that has been in force for a long time, can only be resolved slowly and by degrees, and we must wait patiently. In the next place, we may reckon on the intellectual interest which the patient begins to feel after working for a short time. By explaining things to him, by giving him information about the marvellous world of psychical processes into which we ourselves only gained insight by such analyses, we make him himself into a collaborator, induce him to regard himself with the objective interest of an investigator, and thus push back his resistance, resting as it does on an affective basis. But lastly – and this remains the strongest lever – we must endeavour, after we have discovered the motives for his defence, to deprive them of their value or even to replace them by more powerful ones. This no doubt is where it ceases to be possible to state psychotherapeutic activity in formulas. One works to the best of one's power, as an elucidator (where ignorance has given rise to fear), as a teacher, as the representative of a

freer or superior view of the world, as a father confessor who gives absolution, as it were, by a continuance of his sympathy and respect after the confession has been made. One tries to give the patient human assist-
[283] ance, so far as this is allowed by the capacity of one's own personality and by the amount of sympathy that one can feel for the particular case. It is an essential precondition for such psychical activity that we should have more or less divined the nature of the case and the motives of the defence operating in it, and fortunately the technique of insistence and pressure takes us as far as this. The more such riddles we have already solved, the easier we may find it to guess a new one and the sooner we shall be able to start on the truly curative psychical work. For it is well to recognize this clearly: the patient only gets free from the hysterical symptom by reproducing the pathogenic impressions that caused it and by giving utterance to them with an expression of affect, and thus the therapeutic task *consists solely in inducing him to do so*; when once this task has been accomplished there is nothing left for the physician to correct or to remove. Whatever may be required for this purpose in the way of counter-suggestions has already been expended during the struggle against the resistance. The situation may be compared with the unlocking of a locked door, after which opening it by turning the handle offers no further difficulty.

Besides the intellectual motives which we mobilize to overcome the resistance, there is an affective factor, the personal influence of the physician, which we can seldom do without, and in a number of cases the latter alone is in a position to remove the resistance. The situation here is no different from what it is elsewhere in medicine and there is no therapeutic procedure of which one may say that it can do entirely without the cooperation of this personal factor.

(3)

In view of what I have said in the preceding section about the difficulties of my technique, which I have unsparingly exposed (I brought them together, incidentally, from the severest cases; things often turn out very much more conveniently) – in view of all this, then, everyone will no doubt feel inclined to ask whether it would not be more expedient, instead of putting up with all these troubles, to make a more energetic use of hypnosis or to restrict the use of the cathartic method to patients who can be put under deep hypnosis. As regards the latter proposal I
[284] should have to answer that in that case the number of suitable patients,

so far as *my* skill is concerned, would dwindle far too much; and I would meet the first piece of advice with the suspicion that the forcible imposition of hypnosis might not spare us much resistance. My experiences on this point, oddly enough, have not been numerous, and I cannot, therefore, go beyond a suspicion. But where I have carried out a cathartic treatment under hypnosis instead of under concentration, I did not find that this diminished the work I had to do. Not long ago I completed a treatment of this kind in the course of which I caused a hysterical paralysis of the legs to clear up. The patient passed into a state which was very different psychically from waking and which was characterized physically by the fact that it was impossible for her to open her eyes or get up till I had called out to her: 'Now wake up!' Nonetheless, I have never come across greater resistance than in this case. I attached no importance to these physical signs, and towards the end of the treatment, which lasted ten months, they had ceased to be noticeable. But in spite of this the patient's state while we were working lost none of its psychical[1] characteristics – the capacity she possessed for remembering unconscious material and her quite special relation to the figure of the physician. On the other hand, I have given an example in the case history of Frau Emmy von N. of a cathartic treatment in the deepest somnambulism in which resistance played scarcely any part. But it is also true that I learnt from that lady nothing whose telling might have called for any special overcoming of objections, nothing that she could not have told me even in a waking state, supposing we had been acquainted for some time and she had thought fairly highly of me. I never reached the true causes of her illness, which were no doubt identical with the causes of her relapse after my treatment (for this was my first attempt with this method); and the only occasion on which I happened to ask her for a reminiscence which involved an erotic element [p. 70 above] I found her just as reluctant and untrustworthy in what she told me as I did later with any of my non-somnambulistic patients. I have already spoken in that lady's case history of the resistance which she put up even during somnambulism to other requests and suggestions of mine. I have become altogether sceptical about the value of hypnosis in facilitating cathartic treatments, since I have experienced instances in which during deep [285] somnambulism there has been absolute *therapeutic* recalcitrance, where in other respects the patient has been perfectly obedient. I reported a case of this kind briefly on p. 88 *n.*, and I could add others. I may admit, too, that this experience has corresponded pretty well to the

1 ['Psychical' in the first edition only; omitted in all the later editions.]

requirement I insist upon that there shall be a quantitative relation between cause and effect in the psychical field as well [as in the physical one].[1]

In what I have hitherto said the idea of resistance has forced its way into the foreground. I have shown how, in the course of our therapeutic work, we have been led to the view that hysteria originates through the repression of an incompatible idea from a motive of defence. On this view, the repressed idea would persist as a memory trace that is weak (has little intensity), while the affect that is torn from it would be used for a somatic innervation. (That is, the excitation is 'converted'.) It would seem, then, that it is precisely through its repression that the idea becomes the cause of morbid symptoms – that is to say, becomes pathogenic. A hysteria exhibiting this psychical mechanism may be given the name of 'defence hysteria'.

Now both of us, Breuer and I, have repeatedly spoken of two other kinds of hysteria, for which we have introduced the terms 'hypnoid hysteria' and 'retention hysteria'. It was hypnoid hysteria which was the first of all to enter our field of study. I could not, indeed, find a better example of it than Breuer's first case, which stands at the head of our case histories.[2] Breuer has put forward for such cases of hypnoid hysteria a psychical mechanism which is substantially different from that of defence by conversion. In his view what happens in hypnoid hysteria is that an idea becomes pathogenic because it has been received during a special psychical state and has from the first remained outside the ego. No psychical force has therefore been required in order to keep it apart from the ego and no resistance need be aroused if we introduce it into the ego with
[286] the help of mental activity during somnambulism. And Anna O.'s case history in fact shows no sign of any such resistance.

I regard this distinction as so important that, on the strength of it, I willingly adhere to this hypothesis of there being a hypnoid hysteria. Strangely enough, I have never in my own experience met with a genuine hypnoid hysteria. Any that I took in hand has turned into a defence hysteria. It is not, indeed, that I have never had to do with symptoms which demonstrably arose during dissociated states of consciousness and were obliged for that reason to remain excluded from the ego. This was sometimes so in my cases as well; but I was able to show afterwards that the

1 [Some remarks on the length of the period during which Freud made use of the techniques of 'pressure' and hypnotism respectively can be found above in a footnote on p. 98.]

2 [The last nine words are omitted in the German collected editions, *GS*, 1925, and *GW*, 1952, in which the case of Anna O. is not included.]

so-called hypnoid state owed its separation to the fact that in it a psychical group had come into effect which had previously been split off by defence. In short, I am unable to suppress a suspicion that somewhere or other the roots of hypnoid and defence hysteria come together, and that there the primary factor is defence. But I know [*weiss*][1] nothing about this.

My judgement is for the moment equally uncertain as regards 'retention hysteria',[2] in which the therapeutic work is supposed equally to proceed without resistance. I had a case which I looked upon as a typical retention hysteria and I rejoiced in the prospect of an easy and certain success. But this success did not occur, though the work was in fact easy. I therefore suspect, though once again subject to all the reserve which is proper to ignorance, that at the basis of retention hysteria, too, an element of defence is to be found which has forced the whole process in the direction of hysteria. It is to be hoped that fresh observations will soon decide whether I am running the risk of falling into one-sidedness and error in thus favouring an extension of the concept of defence to the whole of hysteria.

I have dealt so far with the difficulties and technique of the cathartic method, and I should like to add a few indications as to the form assumed by an analysis when this technique is adopted. For me this is a highly interesting subject, but I cannot expect it to arouse similar interest in others, who have not yet carried out an analysis of this kind. I shall, it is true, once more be talking about the technique, but this time it will be [287] about inherent difficulties for which we cannot hold the patients responsible and which must be partly the same in a hypnoid or retention hysteria as in the defence hysterias which I have before my eyes as a model. I approach this last part of my exposition with the expectation that the psychical characteristics which will be revealed in it may one day acquire a certain value as raw material for the dynamics of ideation.

The first and most powerful impression made upon one during such an analysis is certainly that the pathogenic psychical material which has ostensibly been forgotten, which is not at the ego's disposal and which plays no part in association and memory, nevertheless in some fashion lies ready to hand and in correct and proper order. It is only a question of removing the resistances that bar the way to the material. In other

1 [This word is translated as 'can say' in *SE*.]

2 [Cf. above, p. 188 and *n*. 3.]

respects this material is known,[1] in the same way in which we are able to know anything; the correct connections between the separate ideas and between them and the non-pathogenic ones, which are frequently remembered, are in existence; they have been completed at some time and are stored up in the memory. The pathogenic psychical material appears to be the property of an intelligence which is not necessarily inferior to that of the normal ego. The appearance of a second personality is often presented in the most deceptive manner.

Whether this impression is justified, or whether in thinking this we are not dating back to the period of the illness an arrangement of the psychical material which in fact was made after recovery – these are questions which I should prefer not to discuss as yet, and not in these pages. The observations made during such analyses can in any case be most conveniently and clearly described if we regard them from the position that we are able to assume after recovery for the purpose of surveying the case as a whole.

As a rule, indeed, the situation is not as simple as we have represented it in particular cases – for instance, where there is one symptom only, which has arisen from one major trauma. We do not usually find a *single* hysterical symptom, but a number of them, partly independent of one another and partly linked together. We must not expect to meet with a
[288] *single* traumatic memory and a *single* pathogenic idea as its nucleus; we must be prepared for *successions* of *partial* traumas and *concatenations* of pathogenic trains of thought. A monosymptomatic traumatic hysteria is, as it were, an elementary organism, a unicellular creature, as compared with the complicated structure of such comparatively severe[2] neuroses as we usually meet with.

The psychical material in such cases of hysteria presents itself as a structure [*Gebilde*][T] in several dimensions which is stratified in at least three different ways. (I hope I shall presently be able to justify this pictorial mode of expression.) To begin with there is a nucleus consisting in memories of events or trains of thought in which the traumatic factor has culminated or the pathogenic idea has found its purest manifestation. Round this nucleus we find what is often an incredibly profuse amount of other mnemic material which has to be worked through in the analysis and which is, as we have said, arranged in a threefold order.

1 ['*gewusst*' ('known') in the first edition only. In all later German editions '*bewusst*' ('conscious'), which seems to make much less good sense.]

2 ['*schwereren*' ('comparatively severe') in the first and second editions only; '*schweren*' ('severe') in all later editions.]

In the first place there is an unmistakable linear chronological order which obtains within each separate theme. As an example of this I will merely quote the arrangement of the material in Breuer's analysis of Anna O. Let us take the theme of becoming deaf, of not hearing. This was differentiated according to seven sets of determinants, and under each of these seven headings ten to over a hundred individual memories were collected in chronological series (p. 33 f.). It was as though we were examining a dossier that had been kept in good order. The analysis of my patient Emmy von N. contained similar files of memories though they were not so fully enumerated and described. These files form a quite general feature of every analysis and their contents always emerge in a chronological order which is as infallibly trustworthy as the succession of days of the week or names of the month in a mentally normal person. They make the work of analysis more difficult by the peculiarity that, in reproducing the memories, they reverse the order in which these originated. The freshest and newest experience in the file appears first, as an outer cover, and last of all comes the experience with which the series in fact began.

I have described such groupings of similar memories into collections [289]
arranged in linear sequences (like a file of documents, a packet, etc.) as constituting 'themes'. These themes exhibit a second kind of arrangement. Each of them is – I cannot express it in any other way – stratified concentrically round the pathogenic nucleus. It is not hard to say what produces this stratification, what diminishing or increasing magnitude is the basis of this arrangement. The contents of each particular stratum are characterized by an equal degree of resistance, and that degree increases in proportion as the strata are nearer to the nucleus. Thus there are zones within which there is an equal degree of modification of consciousness, and the different themes extend across these zones. The most peripheral strata contain the memories (or files), which, belonging to different themes, are easily remembered and have always been clearly conscious. The deeper we go the more difficult it becomes for the emerging memories to be recognized, till near the nucleus we come upon memories which the patient disavows [*verleugnet*]^{T} even in reproducing them.

It is this peculiarity of the concentric stratification of the pathogenic psychical material which, as we shall hear, lends to the course of these analyses their characteristic features. A third kind of arrangement has still to be mentioned – the most important, but the one about which it is least easy to make any general statement. What I have in mind is an arrangement according to thought content, the linkage made by a logical

[*logischen*][1] thread which reaches as far as the nucleus and tends to take an irregular and twisting path, different in every case. This arrangement has a dynamic character, in contrast to the morphological one of the two stratifications mentioned previously. While these two would be represented in a spatial diagram by a continuous line, curved or straight, the course of the logical chain would have to be indicated by a broken line which would pass along the most roundabout paths from the surface to the deepest layers and back, and yet would in general advance from the periphery to the central nucleus, touching at every intermediate halting place – a line resembling the zigzag line in the solution to a knight's move problem, which cuts across the squares in the diagram of the chessboard.

I must dwell for a moment longer on this last simile in order to emphasize a point in which it does not do justice to the characteristics of the [290] subject of the comparison. The logical chain corresponds not only to a zigzag, twisted line, but rather to a ramifying system of lines and more particularly to a converging one. It contains nodal points at which two or more threads meet and thereafter proceed as one; and as a rule several threads which run independently, or which are connected at various points by side-paths, debouch into the nucleus. To put this in other words, it is very remarkable how often a symptom is determined in several ways, is 'overdetermined'.[2]

My attempt to demonstrate the organization of the pathogenic psychical material will be complete when I have introduced one more complication. For it can happen that there is more than one nucleus in the pathogenic material – if, for instance, we have to analyse a second outbreak of hysteria which has an aetiology of its own but is nevertheless connected with a first outbreak of acute hysteria which was got over years earlier. It is easy to imagine, if this is so, what additions there must be to the strata and paths of thought in order to establish a connection between the two pathogenic nuclei.

I shall now make one or two further remarks on the picture we have just arrived at of the organization of the pathogenic material. We have said that this material behaves like a foreign body, and that the treatment, too, works like the removal of a foreign body from the living tissue. We are now in a position to see where this comparison fails. A foreign body does not enter into any relation with the layers of tissue that surround it, although it modifies them and necessitates a reactive

1 [The sense seems to imply 'semantic'.]

2 ['*Überbestimmt*.' See footnote 1, p. 189 above.]

inflammation in them. Our pathogenic psychical group, on the other hand, does not admit of being cleanly extirpated from the ego. Its external strata pass over in every direction into portions of the normal ego; and, indeed, they belong to the latter just as much as to the pathogenic organization. In analysis the boundary between the two is fixed purely conventionally, now at one point, now at another, and in some places it cannot be laid down at all. The interior layers of the pathogenic organization are increasingly alien to the ego, but once more without there being any visible boundary at which the pathogenic material begins. In fact the pathogenic organization does not behave like a foreign body, but far more like an infiltrate. In this simile the resistance must be regarded as what is infiltrating. Nor does the treatment consist in extirpating [291] something – psychotherapy is not able to do this for the present – but in causing the resistance to melt and in thus enabling the circulation to make its way into a region that has hitherto been cut off.

(I am making use here of a number of similes, all of which have only a very limited resemblance to my subject and which, moreover, are incompatible with one another. I am aware that this is so, and I am in no danger of overestimating their value. But my purpose in using them is to throw light from different directions on a highly complicated topic which has never yet been represented. I shall therefore venture to continue in the following pages to introduce similes in the same manner, though I know this is not free from objection.)[1]

If it were possible, after the case had been completely cleared up, to demonstrate the pathogenic material to a third person in what we now know is its complicated and multidimensional organization, we should rightly be asked how a camel like this got through the eye of the needle. For there is some justification for speaking of the 'defile' of consciousness. The term gains meaning and liveliness for a physician who carries out an analysis like this. Only a single memory at a time can enter ego consciousness. A patient who is occupied in working through such a memory sees nothing of what is pushing after it and forgets what has already pushed its way through. If there are difficulties in the way of mastering this single pathogenic memory – as, for instance, if the patient does not relax his resistance against it, if he tries to repress or mutilate it – then the defile is, so to speak, blocked. The work is at a standstill, nothing more can appear, and the single memory which is in process of breaking through remains in front of the patient until he has taken it up

1 [Here Freud seems to be adumbrating what he will later call 'metapsychological' descriptions of the mental apparatus and its workings.]

into the breadth of his ego. The whole spatially extended mass of psychogenic material is in this way drawn through a narrow cleft and thus arrives in consciousness cut up, as it were, into pieces or strips. It is the psychotherapist's business to put these together once more into the organization which he presumes to have existed. Anyone who has a craving for further similes may think at this point of a Chinese puzzle.

If we are faced with starting such an analysis, in which we have reason to expect an organization of pathogenic material like this, we shall be [292] assisted by what experience has taught us, namely that *it is quite hopeless to try to penetrate directly to the nucleus of the pathogenic organization*. Even if we ourselves could guess it, the patient would not know what to do with the explanation offered to him and would not be psychologically changed by it.

There is nothing for it but to keep at first to the periphery of the psychical structure. We begin by getting the patient to tell us what he knows and remembers, while we are at the same time already directing his attention and overcoming his slighter resistances by the use of the pressure procedure. Whenever we have opened a new path by thus pressing on his forehead, we may expect him to advance some distance without fresh resistance.

After we have worked in this way for some time, the patient begins as a rule to cooperate with us. A great number of reminiscences now occur to him, without our having to question him or set him tasks. What we have done is to make a path to an inner stratum within which the patient now has spontaneously at his disposal material that has an equal degree of resistance attaching to it. It is best to allow him for a time to reproduce such material without being influenced. It is true that he himself is not in a position to uncover important connections, but he may be left to clear up material lying within the same stratum. The things that he brings up in this way often seem disconnected, but they offer material which will be given point when a connection is discovered later on.

Here we have in general to guard against two things. If we interfere with the patient in his reproduction of the ideas that pour in on him, we may 'bury' things that have to be freed later with a great deal of trouble. On the other hand we must not overestimate the patient's unconscious 'intelligence' and leave the direction of the whole work to it. If I wanted to give a diagrammatic picture of our mode of operation, I might perhaps say that we ourselves undertake the opening up of inner strata, advancing *radially*, whereas the patient looks after the *peripheral* extension of the work.

Advances are brought about, as we know, by overcoming resistance in the manner already indicated. But before this, we have as a rule another task to perform. We must get hold of a piece of the logical thread, by whose guidance alone we may hope to penetrate to the interior. We cannot expect that the free communications made by the patient, the [293] material from the most superficial strata, will make it easy for the analyst to recognize at what points the path leads into the depths or where he is to find the starting points of the connections of thought of which he is in search. On the contrary. This is precisely what is carefully concealed; the account given by the patient sounds as if it were complete and self-contained. It is at first as though we were standing before a wall which shuts out every prospect and prevents us from having any idea whether there is anything behind it, and if so, what.

But if we examine with a critical eye the account that the patient has given us without much trouble or resistance, we shall quite infallibly discover gaps and imperfections in it. At one point the train of thought will be visibly interrupted and patched up by the patient as best he may, with a turn of speech or an inadequate[1] explanation; at another point we come upon a motive which would have to be described as a feeble one in a normal person. The patient will not recognize these deficiencies when his attention is drawn to them. But the physician will be right in looking behind the weak spots for an approach to the material in the deeper layers and in hoping that he will discover precisely there the connecting threads which he is seeking with the pressure procedure. Accordingly, we say to the patient: 'You are mistaken; what you are putting forward can have nothing to do with the present subject. We must expect to come upon something else here, and this will occur to you under the pressure of my hand.'

For we may make the same demands for logical connection and sufficient motivation in a train of thought, even if it extends into the unconscious, from a hysterical patient as we should from a normal individual. It is not within the power of a neurosis to relax these relations. If the chains of ideas in neurotic and particularly in hysterical patients produce a different impression, if in them the relative intensity of different ideas seems inexplicable by psychological determinants alone, we have already found out the reason for this and can attribute it to *the existence of hidden unconscious motives*. We may thus suspect the presence of such secret motives wherever a breach of this kind in a train of thought is apparent or when the force ascribed by the patient to his motives goes far beyond the normal.

1 [In the first edition only, 'a quite inadequate'.]

[294] In carrying out this work we must of course keep free from the theoretical prejudice that we are dealing with the abnormal brains of '*dégénérés*' *and* '*déséquilibrés*',[1] who are at liberty, owing to a stigma, to throw overboard the common psychological laws that govern the connection of ideas and in whom one chance idea may become exaggeratedly intense for no motive and another may remain indestructible for no psychological reason. Experience shows that the contrary is true of hysteria. Once we have discovered the concealed motives, which have often remained unconscious, and have taken them into account, nothing that is puzzling or contrary to rule remains in hysterical connections of thought, any more than in normal ones.

In this way, then, by detecting lacunas in the patient's first description, lacunas which are often covered by 'false connections' [see below, p. 269], we get hold of a piece of the logical thread at the periphery, and from this point on we clear a further path by the pressure technique.

In doing this, we very seldom succeed in making our way right into the interior along one and the same thread. As a rule it breaks off halfway: the pressure fails and either produces no result or one that cannot be clarified or carried further in spite of every effort. We soon learn, when this happens, to avoid the mistakes into which we might fall. The patient's facial expression must decide whether we have really come to an end, or whether this is an instance which requires no psychical elucidation, or whether what has brought the work to a standstill is excessive resistance. In the last case, if we cannot promptly overcome the resistance we may assume that we have followed the thread down to[2] a stratum which is for the time being still impenetrable. We drop it and take up another thread, which we may perhaps follow equally far. When we have arrived at this stratum along all the threads and have discovered the entanglements on account of which the separate threads could not be followed any further in isolation, we can think of attacking the resistance before us afresh.

It is easy to imagine how complicated a work of this kind can become. We force our way into the internal strata, overcoming resistances all the time; we get to know the themes accumulated in one of these strata and
[295] the threads running through it, and we experiment how far we can advance with our present means and the knowledge we have acquired; we obtain preliminary information about the contents of the next strata by means of the pressure technique; we drop threads and pick them up

1 ['Degenerate' and 'unbalanced' persons. The view then currently held by French psychopathologists.]

2 [*hinauf* ('down to'), changed to *hinein* ('into') in the *GS* and later German editions, and in the *SE*.]

again; we follow them as far as nodal points; we are constantly making up arrears; and every time that we pursue a file of memories we are led to some side-path, which nevertheless eventually joins up again. By this method we at last reach a point at which we can stop working in strata and can penetrate by a main path straight to the nucleus of the pathogenic organization. With this the struggle is won, though not yet ended. We must go back and take up the other threads and exhaust the material. But now the patient helps us energetically. His resistance is for the most part broken.

In these later stages of the work it is of use if we can guess the way in which things are connected up and tell the patient before we have uncovered it. If we have guessed right, the course of the analysis will be accelerated; but even a wrong hypothesis helps us on, by compelling the patient to take sides and by enticing him into energetic denials which betray his undoubtedly better knowledge.

We learn with astonishment from this that *we are not in a position to force anything on the patient about the things of which he is ostensibly ignorant or to influence the products of the analysis by arousing an expectation*. I have never once succeeded, by foretelling something, in altering or falsifying the reproduction of memories or the connection of events; for if I had, it would inevitably have been betrayed in the end by some contradiction in the material. If something turned out as I had foretold, it was invariably proved by a great number of unimpeachable reminiscences that I had done no more than guess right. We need not be afraid, therefore, of telling the patient what we think his next connection of thought is going to be. It will do no harm.

Another observation, which is constantly repeated, relates to the patient's spontaneous reproductions. It may be asserted that every single reminiscence which emerges during an analysis of this kind has significance. An intrusion of *irrelevant* mnemic images (which happen in some way or other to be associated with the important ones) in fact never occurs. An exception which does not contradict this rule may be postulated for memories which, unimportant in themselves, are nevertheless indispensable as a bridge, in the sense that the association between two [296]
important memories can only be made through them.

The length of time during which a memory remains in the narrow defile in front of the patient's consciousness is, as has already been explained [p. 259 above], in direct proportion to its importance. A picture which refuses to disappear is one which still calls for consideration, a thought which cannot be dismissed is one that needs to be pursued

further. Moreover, a recollection never returns a second time once it has been dealt with; an image that has been 'talked away' is not seen again. If nevertheless this does happen we can confidently assume that the second time the image will be accompanied by a new set of thoughts, or the idea will have new implications. In other words, they have not been completely dealt with. Again, it frequently happens that an image or thought will reappear in different degrees of intensity, first as a hint and later with complete clarity. This, however, does not contradict what I have just asserted.

Among the tasks presented by analysis is that of getting rid of symptoms which are capable of increasing in intensity or of returning: pains, symptoms (such as vomiting) which are due to stimuli, sensations or contractures. While we are working at one of these symptoms we come across the interesting and not undesired phenomenon of 'joining in the conversation'.[1] The problematical symptom reappears, or appears with greater intensity, as soon as we reach the region of the pathogenic organization which contains the symptom's aetiology, and thenceforward it accompanies the work with characteristic oscillations which are instructive to the physician. The intensity of the symptom (let us take for instance a desire to vomit) increases the deeper we penetrate into one of the relevant pathogenic memories; it reaches its climax shortly before the patient gives utterance to that memory; and when he has finished doing so it suddenly diminishes or even vanishes completely for a time. If, owing to resistance, the patient delays his telling for a long time, the tension of the sensation – of the desire to vomit – becomes unbearable, and if we cannot force him to speak he actually begins to vomit. In this
[297] way we obtain a plastic impression of the fact that 'vomiting' takes the place of a psychical act (in this instance, the act of utterance), exactly as the conversion theory of hysteria maintains.

This oscillation in intensity on the part of the hysterical symptom is then repeated every time we approach a fresh memory which is pathogenic in respect of it. The symptom, we might say, is on the agenda all the time. If we are obliged temporarily to drop the thread to which this symptom is attached, the symptom, too, retires into obscurity, to emerge once more at a later period of the analysis. This performance goes on until the working over of the pathogenic material disposes of the symptom once and for all.

1 [An example of this can be found in the case history of Fräulein Elisabeth von R. (p. 132 above). It is also mentioned by Breuer on p. 34.]

In all this, strictly speaking, the hysterical symptom is not behaving in any way differently from the memory picture or the reproduced thought which we conjure up under the pressure of our hand. In both cases we find the same obsessionally obstinate [*obsedierende Hartnäckigkeit*] recurrence in the patient's memory, which has to be disposed of. The difference lies only in the apparently spontaneous emergence of the hysterical symptoms, while, as we very well remember, we ourselves provoked the scenes and ideas. In fact, however, there is an uninterrupted series, extending from the unmodified *mnemic residues* of affective experiences and acts of thought to the hysterical symptoms, which are the *mnemic symbols* of those experiences and thoughts.

The phenomenon of hysterical symptoms joining in the conversation during the analysis involves a practical drawback, to which we ought to be able to reconcile the patient. It is quite impossible to effect an analysis of a symptom at a single stretch or to distribute the intervals in our work so that they fit in precisely with pauses in the process of dealing with the symptom. On the contrary, interruptions which are imperatively prescribed by incidental circumstances in the treatment, such as the lateness of the hour, often occur at the most inconvenient points, just as one may be approaching a decision or just as a new topic emerges. Every newspaper reader suffers from the same drawback in reading the daily instalment of his serial story, when, immediately after the heroine's decisive speech or after the shot has rung out, he comes upon the words: 'To be continued.' In our own case the topic that has been raised but not dealt with, the symptom that has become temporarily intensified and has not yet been explained, persists in the patient's mind [*Seelenleben*][T] and [298] *Seele*
may perhaps be more troublesome to him than it has otherwise been. He[1] will simply have to make the best of this; there is no other way of arranging things. There are patients who, in the course of an analysis, simply cannot get free of a topic that has once been raised and who are obsessed [*obsedierent*] by it in the interval between two treatments; since by themselves they cannot take any steps towards getting rid of it, they suffer more, to begin with, than they did before the treatment. But even such patients learn in the end to wait for the doctor and to shift all the interest that they feel in getting rid of the pathogenic material on to the hours of treatment, after which they begin to feel freer in the intervals.

1 ['*Er*' ('he') in the first and second editions. '*Es*' ('it', evidently a misprint) in the third edition. This was changed to '*Man*' ('one') in the 1924 edition, perhaps in order to make sense of the '*es*'; but the meaning was now somewhat changed from the original one.]

The general condition of patients during an analysis of this kind also deserves notice. For a time it is uninfluenced by the treatment and continues to be an expression of the factors that were operative earlier. But after this there comes a moment when the treatment takes hold of the patient; it grips his interest, and thenceforward his general condition becomes more and more dependent on the state of the work. Every time something new is elucidated or an important stage in the process [*Gliederung*] of the analysis is reached, the patient, too, feels relieved and enjoys a foretaste, as it were, of his approaching liberation. Every time the work halts and confusion threatens, the psychical burden by which he is oppressed increases; his feeling of unhappiness and his incapacity for work grow more intense. But neither of these things happens for more than a short time. For the analysis proceeds, disdaining to boast because the patient feels well for the time being and going on its way regardless of his periods of gloom. We feel glad, in general, when we have replaced the spontaneous oscillations in his condition by oscillations which we ourselves have provoked and which we understand, just as we are glad when we see the spontaneous succession of symptoms replaced by an order of the day which corresponds to the state of the analysis.

To begin with, the work becomes more obscure and difficult, as a rule, [299] the deeper we penetrate into the stratified psychical structure [*Gebilde*] which I have described above. But once we have worked our way as far as the nucleus, light dawns and we need not fear that the patient's general condition will be subject to any severe periods of gloom. But the reward of our labours, the cessation of the symptoms, can only be expected when we have accomplished the complete analysis of every individual symptom; and indeed, if the individual symptoms are interconnected at numerous nodal points, we shall not even be encouraged during the work by partial successes. Thanks to the abundant causal connections, every pathogenic idea which has not yet been got rid of operates as a motive for the whole of the products of the neurosis, and it is only with the last word of the analysis that the whole clinical picture vanishes, just as happens with memories that are reproduced individually.

If a pathogenic memory or a pathogenic connection which had formerly been withdrawn from the ego consciousness [*Ich-Bewusstsein*] is uncovered by the work of the analysis and introduced into the ego, we find that the psychical personality which is thus enriched has various ways of expressing itself with regard to what it has acquired. It happens particularly often that, after we have laboriously forced some piece of

knowledge on a patient, he will declare: 'I've always known that, I could have told you that before.' Those with some degree of insight recognize afterwards that this is a piece of self-deception and blame themselves for being ungrateful. Apart from this, the attitude adopted by the ego to its new acquisition depends in general on the stratum of analysis from which that acquisition originates. Things that belong to the external strata are recognized without difficulty; they had, indeed, always remained in the ego's possession, and the only novelty to the ego is their connection with the deeper strata of pathological material. Things that are brought to light from these deeper strata are also recognized and acknowledged, but often only after considerable hesitations and doubts. Visual memory images are of course more difficult to disavow [*Verleugnen*] than the memory traces of mere trains of thought. Not at all infrequently the patient begins by saying: 'It's possible that I thought this, but I can't remember having done so.' And it is not until he has been familiar with the hypothesis for some time that he comes to recognize it as well; he remembers – and confirms the fact, too, by subsidiary links – that he really did once have the thought. I make it a rule, however, during the analysis to keep my estimate of the reminiscence that comes up independent of the patient's acknowledgement of it. I shall never be tired of repeating that we are bound to accept whatever our procedure brings to light. If there is anything in it that is not genuine or correct, the context will later on tell us to reject it. But I may say in passing that I have scarcely ever had occasion to disavow subsequently [*nachträglich*] a reminiscence that has been provisionally accepted. Whatever has emerged has, in spite of the most deceptive appearance of being a glaring contradiction, nevertheless turned out to be correct. [300]

The ideas which are derived from the greatest depth and which form the nucleus of the pathogenic organization are also those which are acknowledged as memories by the patient with greatest difficulty. Even when everything is finished and the patients have been overborne by the force of logic and have been convinced by the therapeutic effect accompanying the emergence of precisely these ideas – when, I say, the patients themselves accept the fact that they thought this or that, they often add: 'But I can't *remember* having thought it.' It is easy to come to terms with them by telling them that the thoughts were *unconscious*. But how is this state of affairs to be fitted into our own psychological views? Are we to disregard this withholding of recognition on the part of patients, when, now that the work is finished, there is no longer any motive for their doing so? Or are we to suppose that we are really dealing with thoughts

which never came about, which merely had a *possibility* of existing, so that the treatment would lie in the accomplishment of a psychical act which did not take place at the time? It is clearly impossible to say anything about this – that is, about the state which the pathogenic material was in before the analysis – until we have arrived at a thorough clarification of our basic psychological views, especially on the nature of consciousness. It remains, I think, a fact deserving serious consideration that in our analyses we can follow a train of thought from the conscious into the unconscious (i.e. into something that is absolutely not recognized as a memory), that we can trace it from there for some distance through consciousness once more and that we can see it terminate in the unconscious again, without this alternation of 'psychical illumination' making any change in the train of thought itself, in its logical consistency
[301] and in the interconnection between its various parts. Once this train of thought was before me as a whole I should not be able to guess which part of it was recognized by the patient as a memory and which was not. I only, as it were, see the peaks of the train of thought dipping down into the unconscious – the reverse of what has been asserted of our normal psychical processes.

I have finally to discuss yet another topic, which plays an undesirably large part in the carrying out of cathartic analyses such as these. I have already [p. 250 f. above] admitted the possibility of the pressure technique failing, of its not eliciting any reminiscence in spite of every assurance and insistence. If this happens, I said, there are two possibilities: either, at the point at which we are investigating, there is really nothing more to be found – and this we can recognize from the complete calmness of the patient's facial expression; or we have come up against a resistance which can only be overcome later, we are faced with a new stratum into which we cannot yet penetrate – and this, once more, we can infer from the patient's facial expression, which is tense and gives evidence of mental effort [p. 262]. But there is yet a third possibility which bears witness equally to an obstacle, but an external obstacle, and not one inherent in the material. This happens when the patient's relation to the physician is disturbed, and it is the worst obstacle that we can come across. We can, however, reckon on meeting it in every comparatively serious analysis.

I have already [p. 236 f.] indicated the important part played by the figure of the physician in creating motives to defeat the psychical force of resistance. In not a few cases, especially with women and where it is a

question of elucidating erotic trains of thought, the patient's cooperation becomes a personal sacrifice, which must be compensated by some substitute for love. The trouble taken by the physician and his friendliness have to suffice for such a substitute. If, now, this relation of the patient to the physician is disturbed, her cooperativeness fails [*versagt*] too; when the physician tries to investigate the next pathological idea, the patient is held up by an intervening consciousness of the complaints against the physician that have been accumulating in her. In my experience this obstacle arises in three principal cases.

(1) If there is a personal estrangement – if, for instance, the patient feels she has been neglected, has been too little appreciated or has been insulted, or if she has heard unfavourable comments on the physician or the method of treatment. This is the least serious case. The obstacle can easily be overcome by discussion and explanation, even though the sensitiveness and suspiciousness of hysterical patients may occasionally attain surprising dimensions. [302]

(2) If the patient is seized by a dread of becoming too much accustomed to the physician personally, of losing her independence in relation to him, and even of perhaps becoming sexually dependent on him. This is a more important case, because its determinants are less individual. The cause of this obstacle lies in the special solicitude inherent in the treatment. The patient then has a new motive for resistance, which is manifested not only in relation to some particular reminiscence but at every attempt at treatment. It is quite common for the patient to complain of a headache when we start on the pressure procedure; for her new motive for resistance remains as a rule unconscious and is expressed by the production of a new hysterical symptom. The headache indicates her dislike of allowing herself to be influenced.

(3) If the patient is frightened at finding that she is transferring [*überträgt*][T] on to the figure of the physician the distressing ideas which arise from the content of the analysis. This is a frequent, and indeed in some analyses a regular, occurrence. Transference[1] on to the physician takes place through a *false connection*.[2] I must give an example of this. *Übertragung*

1 [This is the first appearance of 'transference' (*Übertragung*) in the psychoanalytic sense, though it is being used more narrowly here than in Freud's later writings. For a somewhat different use of the term see Chapter VII, Section C, of *The Interpretation of Dreams* (1900*a*), *RSE*, **5**, 503 f. Freud next dealt with the subject of 'transferences' near the end of the last section of the case history of 'Dora' (1905*e*), ibid., **7**, 102 ff.]

2 [*falsche Verknüpfung*. A long account of 'false connections' and the 'compulsion to associate' can be found above in a footnote on p. 60 f. – Freud had already discussed them in relation to obsessions at the beginning of Section II of his first paper on 'The Neuropsychoses of Defence' (1894*a*), *RSE*, **3**, 48 f.]

In one of my patients the origin of a particular hysterical symptom lay in a wish, which she had had many years earlier and had at once relegated
[303] to the unconscious, that the man she was talking to at the time might boldly take the initiative and give her a kiss. On one occasion, at the end of a session, a similar wish came up in her about me. She was horrified at it, spent a sleepless night, and at the next session, though she did not refuse to be treated, was quite useless for work. After I had discovered the obstacle and removed it, the work proceeded further; and lo and behold! the wish that had so much frightened the patient made its appearance as the next of her pathogenic recollections and the one which was demanded by the immediate logical context. What had happened therefore was this. The content of the wish had appeared first of all in the patient's consciousness without any memories of the surrounding circumstances which would have assigned it to a past time. The wish which was present was then, owing to the compulsion to associate [*Assoziationszwang*] which was dominant in her consciousness, linked to my person, with which the patient was legitimately concerned; and as the result of this *mésalliance* – which I describe as a 'false connection' – the same affect was provoked which had forced the patient long before to repudiate this forbidden wish. Since I have discovered this, I have been able, whenever I have been similarly involved personally, to presume that a transference and a false connection have once more taken place. Strangely enough, the patient is deceived afresh every time this is repeated.

It is impossible to carry any analysis to a conclusion unless we know how to meet the resistance arising in these three ways. But we can find a way of doing so if we make up our minds that this new symptom that has been produced on the old model must be treated in the same way as the old symptoms. Our first task is to make the 'obstacle' conscious to the patient. In one of my patients, for instance, the pressure procedure suddenly failed. I had reason to suppose that there was an unconscious idea of the kind mentioned under (2) above, and I dealt with it at the first attempt by taking her by surprise. I told her that some obstacle must have arisen to continuing the treatment, but that the pressure procedure had at least the power to show her what this obstacle was; I pressed on her head, and she said in astonishment: 'I see you sitting on the chair here; but that's nonsense. What can it mean?' I was then able to enlighten her. With another patient the 'obstacle' used not to appear directly as a result of my pressure, but I was always able to discover it if I took the patient
[304] back to the moment at which it had originated. The pressure procedure never failed to bring this moment back for us. When the obstacle had

been discovered and demonstrated the first difficulty was cleared out of the way. But a greater one remained. It lay in inducing the patient to produce information where apparently personal relations were concerned and where the third person coincided with the figure of the physician.

To begin with I was greatly annoyed at this increase in my psychological work, till I came to see that the whole process followed a law; and I then noticed, too, that transference of this kind brought about no great addition to what I had to do. For the patient the work remained the same: she had to overcome the distressing affect aroused by having been able to entertain such a wish even for a moment; and it seemed to make no difference to the success of the treatment whether she made this psychical repudiation the theme of her work in the historical instance or in the recent one connected with me. The patients, too, gradually learnt to realize that in these transferences on to the figure of the physician it was a question of a compulsion and an illusion which melted away with the conclusion of the analysis. I believe, however, that if I had neglected to make the nature of the 'obstacle' clear to them I should simply have given them a new hysterical symptom – though, it is true, a milder one – in exchange for another which had been generated spontaneously.

I have now given enough indications, I think, of the way in which these analyses have been carried out and of the observations that I have made in the course of them. What I have said may perhaps make some things seem more complicated than they are. Many problems answer themselves when we find ourselves engaged in such work. I did not enumerate the difficulties of the work in order to create an impression that, in view of the demands a cathartic analysis makes on physician and patient alike, it is only worthwhile undertaking one in the rarest cases. I allow my medical activities to be governed by the contrary assumption, though I cannot, it is true, lay down the most definite indications for the application of the therapeutic method described in these pages without entering into an examination of the more important and comprehensive topic of [305] the treatment of the neuroses in general. I have often in my own mind compared cathartic psychotherapy with surgical intervention. I have described my treatments as psychotherapeutic operations; and I have brought out their analogy with the opening up of a cavity filled with pus, the scraping out of a carious region, etc. An analogy of this kind finds its justification not so much in the removal of what is pathological as in the

establishment of conditions that are more likely to lead the course of the process in the direction of recovery.

When I have promised my patients help or improvement by means of a cathartic treatment I have often been faced with this objection: 'Why, you tell me yourself that my illness is probably connected with my circumstances and the events of my life. You cannot alter these in any way. How do you propose to help me, then?' And I have been able to make this reply: 'No doubt fate would find it easier than I do to relieve you of your illness. But you will be able to convince yourself that much will be gained if we succeed in transforming your hysterical misery into common unhappiness. With a mental life[1] that has been restored to health you will be better armed against that unhappiness.'

1 [*Seelenleben*. The German editions previous to 1925 read *Nervensystem* ('nervous system').]

FOUR DOCUMENTS IN THE CASE OF 'NINA R.'

(1978 [1891–94])

EDITORS' NOTE

GERMAN EDITIONS

(1891, 1893, 1894 Presumed dates of composition.)
1978 *Jb. Psychoan.*, **10**, 136–68.
1987 *GW*, **Nachtr.**, 313–21.

The present translation, by Mark Solms, is the first into English.

The archives of the Bellevue sanatorium in Kreuzlingen, Switzerland, were the source of fresh material on Breuer's patient Anna O. (Ellenberger, 1970, 1972; Hirschmüller, 1978*b*). They were also found to contain records of several other patients who had been referred to this institution by Breuer and Freud during the period 1881–1910 (Hirschmüller, 1978*a*).

The four documents reproduced here – the anamnesis, the clinical history, a letter from Freud to Robert Binswanger (then medical director of the sanatorium) and a report by Breuer – relate to one of these patients, to whom Hirschmüller gave the pseudonym 'Nina R.' when he first published them. In addition to these documents, Hirschmüller's paper includes a letter dated March 5, 1889, from the patient to Professor Richard von Krafft-Ebing, describing her condition, as well as an extract from the sanatorium's Clinical Record and two letters from Breuer to Dr Binswanger on the question of gynaecological surgery for the patient.

Breuer, who seems to have been the R. family's general practitioner, treated Nina for suspected peritonitis in 1886 when she was about sixteen years old. Her letter to Krafft-Ebing was written while she was an in-patient (1888–9) at Mariagrün, his private sanatorium near Graz. On July 18, 1893, the patient, then twenty-four years old, was referred by Breuer and Freud to the Bellevue sanatorium, and she left there on October 4, 1894. Freud's case history and Breuer's report are undated but were unquestionably written at the time of the patient's admission to Bellevue.

The anamnesis, which Hirschmüller gives in facsimile (1978*a*, 139–42), is written on the monogrammed notepaper that Freud bought for his correspondence with his fiancée, Martha Bernays (Freud, 1960*a*). It bears no date but from internal evidence can be assigned to the year 1891. Although the anamnesis is in Freud's handwriting, its contents do not seem to be based on his own direct observation of the patient but rather on information obtained at second hand. Moreover, the terminology, diagnostic approach and treatment prescribed are all characteristic of Krafft-Ebing, as his *Lehrbuch der Psychiatrie* (1879–80) confirms.

It is not the general policy of the *RSE* to include such unpublished case material, but it was thought worthwhile in this instance to provide an example of the sort of material in question.

FOUR DOCUMENTS IN THE CASE OF 'NINA R.'

ANAMNESIS 'NINA R.' (1891)

Fräulein R., twenty-one years, very excitable even as a child. Leucorrhoea was observed already (*ex onanismo*!)[1] when she was a three- or four-year-old child – by ten or eleven years, whetted by much masturbation.

Two years ago: fitful sexual excitement with arousal and great excitability. Menstruating by eleven years. Regular thereafter. Has always been exultant, effusive, excitable, and of the opinion that her parents do not like her. Avoided social contact; whenever she was in company, however, she seemed coquettish and animated. Would perspire at the slightest physical effort.

Has always been peculiar, *non sentit, non agit ut ceteri homines*,[2] precocious, secretive, a philosophizer.

In anticipation of social occasions she would vomit from emotion. Whenever she became emotional: immediately felt nauseous. Generally dissatisfied, bored, tired of herself and the world. Breuer, too, recognized masturbation and felt that the patient needed to suppress her excitements (sexual nos[tica])[3] at all costs. When in this state she cannot bear to stay in bed, is highly excited, broods about what happens when one dies, has death crises, feelings as if something has been displaced in her brain. In this state she can eat nothing – loses 2 kg.

She has convulsions in this state. Occasionally imagines Daddy doesn't love her – [then has a] crying fit, generalized convulsion.

Similarly emotional and tearful for years already.

Patient took baths at 25°, which helped but produced some respiratory restriction.

1 ['From masturbation!'.]

2 ['She neither feels nor acts like others.']

3 [Possibly 'sexual nostalgia'.]

Lately she has developed the idea that she must be going mad. She is horrified by [the prospect of] marriage. But when she is courted, she is most charming.

Lately she suffers severely from the obsessional idea that everything is dying off, starting to decay. She is willing to do anything to be rid of this 'mad idea'.

Patient does nothing but read and write.

The patient reports the following. For several years, has had brooding thoughts at night about death and decay – with severe anxiety which she controls only with difficulty. Has also felt downright unhappy and uneasy in other respects. Recently, especially when menstrual, [she has suffered] severe attacks like this, which have become virtually permanent whereas previously she was only troubled by them for half an hour at a time. The thoughts are always the same: everything she sees reminds her of the transitoriness of life – that of others as well as her own – and of death and decay. Has never had olfactory hallucinations. She is visited by this circle of thoughts in the midst of sleep and of conversation. She can see that the situation is pathological and also knows that she is often able to control it. She has always tended to brood. Her obsessive brooding [*Grübelsucht*] is concentrated upon this circle of thoughts alone. She does not experience visions.

During the attacks everything appears illusory and false, everything is unreal; for example, she and everything around her return to nothingness. Then everything earthly, all she does, seems meaningless and ridiculous.

Actually, has always compulsively brooded about herself and the world.

Frequent weariness, weakness, headache. With protracted onslaught of these thoughts, she experiences pressure in the head, too. No spinal irritation. She loves solitude but currently is afraid to be alone; is also very impressionable. Has palpitations, only with the obsessional ideas 'which pursue her like devils'.

Appetite is highly variable, mostly anorectic. No *globus* [*hystericus*] but frequent feeling of respiratory constriction in the upper part of the chest. Sleep is agitated, disturbed by dreams, but is long enough and abundant.

She only enjoys serious reading matter. Reading does not strain her. Menses are prolonged, lasting up to eight days. Postmenstrually she is at her most excitable and uneasy. If [in the past] she could not sleep, she would take chloral [hydrate]; when excited, 0.5 [g.] bromide. The dosage seems too low to her! Half-baths of up to 24° have done her good. Being in the countryside helps.

Patient of average weight. Sexual arousal has diminished almost entirely of late. Signs of anaemia. Average nutrition. Habitually constipated. Tongue consistently clear.

Rx. Half-baths 24°, perhaps also massage, Levico water,[1] 2–3.0 [g.] bromide during attacks.

CLINICAL HISTORY 'NINA R.' (1893)

Fräulein Nina R.

I am unable to provide a complete picture of the patient: (1) because I do not know all the facts – I was not her permanent physician; I treated her only two years ago and currently before her departure, for a few months at a time –; and (2) because the clinical picture is not entirely clear to me. I will limit myself to scattered comments and emphasize a few points.

The patient does not come from particularly good stock. There is considerable hereditary taint on the father's side. The father himself, as far as I know, is not neuropathic; he is also thoroughly honourable but limited – averse to higher intellectual interests no less than to eccentricities. His household is set up for money-making and socializing, with no intellectual stimulation. The mother, a thoroughly good-natured and upright woman, is not neurotic either but is of slight intelligence. The relationship between the two: excellent. A younger brother is also unable to maintain himself owing to a complicated neurosis of a predominantly hysterical nature. A still younger brother has, so to speak, not yet decided.

The *father's nature* (his lack of affection, or at least of demonstrativeness) has created a background of dissatisfaction in the patient with her relationships, and this – I know from her – has laid the foundation of a hysterical anorexia with vomiting in the usual way (fear of mealtimes, these being opportunities for togetherness).[2]

She was always a 'tricky' character. It has been difficult for all the physicians who have treated her to separate her character from her illness. The innate distortion in her nature reveals itself in that she neglects to fulfil her immediate duties and to reconcile herself with her milieu, whereas she constantly endeavours to expand her cerebral interests and to effect higher intellectual stimulation for herself. She was an 'intellectual coquette' but physically a terrible prude. She continued with her

1 [Mineral water from the spa at Levico in South Tyrol, which contained arsenic and was used as a diuretic.]

2 [It is unclear what 'in the usual way' refers to. In other writings from this period, Freud linked hysterical anorexia with disgust, and therefore with repression. The mechanism Freud seems to have in mind is clearly described in (1893*h*), *RSE*, **3**, 32. See some similar remarks by Freud (1895*g*) on p. 295 f. below.]

childhood masturbation up to an age when no doubt could remain in her about the meaning of this act or its accompanying sensations. As is the rule with females, the symptoms of her illness first came to the fore as a consequence of the renunciation of masturbation – [this refers to] general symptoms as well as any reminiscence which is described as an 'irritant' and which is accompanied by distressing sensations.

Masturbation has also stamped the neurasthenic features (which now predominate) on to the entire picture: the many distressing paraesthesias, the eating unpleasure, the exhaustibility at excitement, the manifold fears and the mental state attached to them (which consists in the anxious belief that she has a restricted supply of energy at her disposal and in a resultant daily vigil to ensure that nothing be asked of her which exceeds her strength [*Kräfte*]). She has, in truth, gradually given up everything which makes a young girl happy and retained nothing in life but worries surrounding her health.

These neurasthenic features, however, far from exhaustively describe the picture. An indefinite number of hysterical symptoms (of psychical and motoric type) ensued from the individual experiences that were triggered by her illness and by the attempts that have been made to cure it. Finally, I do not want to exclude organic causes. There was a time (1886) when abdominal pains accompanied by fever suddenly set in. Dr Breuer's diagnosis was peritoneal inflammation due to a suspected Graafian follicle rupture. Dr Fleischmann,[1] who had undertaken an internal gynaecological examination three weeks previously, noticed unilateral swelling of a retroflex uterus. The anorexia apparently only reached its full extent after that peritoneal affection. The menstrual influence upon the general condition has become unmistakable since then and a [vaginal] discharge, which exerted the most distinct influence on the eating difficulty, appeared soon thereafter. On account of these troubles, Dr Fleischmann performed a curettage of the uterus in June, 1893 (cf. his report in this regard).

The patient spent the better part of the years 1887 and 1888[2] in the Mariagrün sanatorium, which was then under Krafft-Ebing's personal direction. It was there, while attempts were being made to hypnotize her, that the symptoms reached their peak and the hysterical attacks broke out. The sojourn at Mariagrün acquired great significance in later years, in that it very much impeded the treatments of succeeding physicians. From then onwards coercion was out of the question; confidence in

1 [Dr Carl Fleischmann, a Viennese gynaecologist.]

2 [This is incorrect; she was an in-patient there in 1888–9 (see Editors' Note, p. 275 above).]

physicians was shattered. The many occasions on which the physicians at the sanatorium had given up trying (after lengthy struggles) and had made concessions were evoked again and again by the patient to support her resolve against her attackers [the physicians]. From then on she became her own physician, perhaps conceding to us the right to console her, to be kind to her and to hear her admonitions – so long as we respected the ceremonials with which she had surrounded herself and did not seek to deprive her of cherished habits. She also criticized us physicians in an utterly ruthless manner and brought to each and every treatment the implacable suspicion: it 'will only do her harm'.

The considerable intelligence of the patient, the vicissitudes of her stay in the institution, the support she received from her thoroughly good-natured mother, and the perpetually repeated assurance that coercion would only do her harm, often occasioned Dr Breuer and me to be very compliant towards her. Her lifestyle up to the time that I took her on again – early in 1893 – was arranged roughly as follows. She lived in a room which led on to a noisy street, with an attendant who was completely under her power; the attendant had, for example, to comfort her at her bidding, pity her, etc. The patient almost never got up, did not go down to the street, anxiously avoided contact with father and brother, and ruthlessly tormented her mother. The poor woman had the task of defending her daughter against the demands of the physician (or else she was accused of being 'heartless') and had to meet all sorts of small requests without return of service. The patient was accustomed to consume plenty of alcohol and only slept with the help of chloral; but she slept badly all the same. As a result, she needed to use the morning [for sleeping] and began the day at her leisure. At mealtimes (the great toil of her day) no-one apart from the attendant was permitted to be present.

Thanks to the eventual revolt of the mother, I (supported by the resolute attendant) was able to get rid of the worst of these habits. The patient herself, incidentally, became ashamed of these aberrations of her condition. Despite her great fear of coercion, new demands and excitement, she has consented to travel to Constance. I promised her that the physicians there would treat her just as humanely and lovingly as we did and that they would not believe that she was malingering or exaggerating. If one shows interest, something can probably be achieved with her.

Opium,[1] which I gave her according to prescription, had a decidedly favourable effect on her mood and on her ability to eat. Alcohol [has

1 [Krafft-Ebing (1879–80) controversially recommended opium in cases of neurasthenia. (Cf. Hirschmüller, 1978*a*, 161 *n*. 62.)]

been] considerably reduced, chloral still remains. Bowel movements are quite painful and are spontaneous only at times of high excitement. She complains of pains in all limbs, due in part to tangible changes in the musculature. The postmenstrual period is the worst.

I asked for her mother to be sent home as soon as possible.

With the hope that this fragmentary contribution has at least provided the first clues for an assessment of the patient,

Respectfully yours,

DR SIGM. FREUD

REPORT ON 'NINA R.' (*BREUER*) (1893)

I have little to add to Dr Freud's report. The hereditary taint on the father's side ought to be significant; the grandmother had a frightful speech (or rather shouting) tic. Uncle and aunt are very neurotic at times. The father himself is healthy.

I believe that there really was once a peritoneal process (haematocele retrouterina?) and that the chronic endometritis (the existence of which is certain) plays a large part in the condition – particularly in its periodicity: the clinical state is at its worst after her period, until the mucosal discharge at mid-cycle, [then there is] vomiting, [then she] improves before her [next] period.

Morally, Nina is an example of the well-known type of 'vivacious Jewish girl', who falls out with her family through self-overvaluation and egoism (too limited capacity for love). However, considering her intelligence, there is room for hope – the impersonal discipline of the institution and, above all, its moral calm, really ought to help her get on.

Her own case history as well as the pencil-written notes are the property of Prof. von Krafft-Ebing (4 Maximilianplatz) and I do beg you to return them to him.

With kind regards, and asking for goodwill towards the patient,

J. BREUER

LETTER TO ROBERT BINSWANGER (1894)

Dear Colleague,

I am not entirely out of contact with R., whose daughter we sent with such effort last year to your institution. The letters which she writes home and the reports which our colleague von Holst[1] sends to the parents are passed on to me. I have now recently been asked by the patient's parents to approach you for accurate information about her clinical status. Owing to the death of one of their sons,[2] a great deal has changed at home and I see that the inclination to having Nina come home is greater than before.

I have no choice but to ask you for such a report. I know what a nuisance I am being to you (or your assistants) but I am counting on kind consideration of the demands being made upon me.

Faithfully and respectfully yours,

DR FREUD

1 [Otto von Holst (1861–1910), assistant physician at Bellevue from 1890.]

2 [The older of Nina's two brothers.]

TWO CONTEMPORARY REPORTS OF A THREE-PART LECTURE 'ON HYSTERIA'

(1895)

EDITORS' INTRODUCTION

ÜBER HYSTERIE

GERMAN EDITIONS

1895 *Wien. klin. Rdsch.*, **9** (42), 662–3, (43), 679–80, and (44), 696–7. (October 20, 27 and November 3.)
1895 *Wien. med. Presse*, **36** (43), 1638–41, and (44), 1678–9. (October 27 and November 3.)
1987 *GW*, **Nachtr.**, 328–51.

The present translation, by Mark Solms, is the first into English.

Freud delivered a lecture 'On Hysteria' in three parts on October 14, 21 and 28, 1895, at the Wiener medizinisches Doktorencollegium (Vienna College of Physicians). There followed a discussion, in two sessions, on November 4 and 11. In addition to the two lengthy reports printed here, briefer accounts appeared in the *Wiener medizinische Blätter*, **18** (1895), 684 and 701–2, in the *Wiener medizinsche Wochenschrift*, **45** (1895), 1995–7, and in the *Medizinische Neuigkeiten* (Munich), **45** (1895), 385–9 and 393–4. The ensuing sessions devoted to discussion were fully reported in the *Wiener klinische Rundschau*, **9** (1895), 711 and 728, and in the *Wiener medizinische Presse*, **36** (1895), 1717–18 and 1757–8. The *Wiener medizinische Blätter*, **18** (1895), 716–17, gave full reports of only the first of the two discussion evenings. (The other periodicals listed above did not carry full reports of the discussion.)

There are two confusing errors in the dating of the reports. The date of the third part of the lecture on October 28 is given wrongly in the *Wiener medizinische Presse* as October 26, and the second session of the discussion is reported by the *Wiener klinische Rundschau* as having taken place on November 10 instead of November 11.

The report of the lecture given in the *Wiener medizinische Presse* has been summarized and discussed by Andersson (1962, 187 ff.). Sulloway (1979, Appendix A, 507–9) has translated the accounts of Breuer's contribution to the discussion on November 4, which were published in the *Wiener medizinische Presse* and the *Wiener medizinische Blätter*.

We know that Freud did not intend to publish the lecture. In a letter to Fliess dated October 20, 1895, and continued on October 21, he writes: 'Today I gave my second lecture on hysteria, making repression the central point. They liked it, but I shall not have it published' (Freud, 1950*a*, Letter 32). The two reports of the lecture, in the

Rundschau and the *Presse*, are described in each case as an original report. In neither case is there any external evidence, from letters to Fliess or from other sources, that Freud had a hand in the composition of these abstracts or that he revised them for publication. From internal evidence, his authorship can be regarded as highly unlikely, since both abstracts are in different ways deficient. Reading both together, it is possible to obtain a clearer picture of the original lecture than is available from either alone, and this fact led to the decision to print both versions here. The *Presse* report, which is more condensed and systematic, omits the illustrations drawn from clinical histories and the analogies so characteristic of Freud's style. The *Rundschau* account, which Ellenberger (1970, 471) attributes to Arthur Schnitzler, while retaining these vivid details, has some small but important omissions and errors. For example, it fails to make clear that the pressure technique was Freud's own preferred method, not Breuer's, and that the term 'splitting of psychical activity', attributed to Breuer, was a replacement for the unsatisfactory 'splitting of consciousness'. The term 'hypnoid moments' is not used, and in one passage it prints '*Zwangsneurose*' ('obsessional neurosis') instead of '*Angstneurose*' ('anxiety neurosis'), a mistake which Freud could scarcely have overlooked had his approval been sought for the abstract.

There is very little else in the Fliess correspondence about the lecture and the content thereof, apart from the brief allusion quoted above. However, in a letter to Fliess of October 31, 1895, Freud wrote: 'I recently perpetrated three lectures on hysteria in which I was very impudent' (Freud, 1950*a*, Letter 33). Andersson (1962, 189) convincingly interprets this as a reference to Freud's exposition, for the first time in public, of the mechanism by which childhood experiences, whose sexual nature was not recognized at the time, became activated after or at the time of puberty, giving rise after the fact (*nachträglich*) to the formation of hysterical or obsessional symptoms.

The lecture, divided into three parts for the purpose of delivery, nonetheless forms a coherent whole, in which Freud summarizes and recapitulates findings which he had already published in his papers on anxiety neurosis (1895*b* [1894], 1895*f*) and in the *Studies on Hysteria* (1895*d*). It also contains a wealth of material which was to be further explored in the three papers of the following year: 'Heredity and the Aetiology of the Neuroses' (1896*a*), the second paper on 'The Neuropsychoses of Defence' (1896*b*) and 'The Aetiology of Hysteria' (1896*c*). The relationship with the 'Project' (1950*a*) is particularly close, and it should be recalled that it was only six days before the delivery of the first part of the lecture that Freud had sent Fliess the surviving manuscript of the 'Project', on October 8. The links with these and other works are pointed out in more detail in the editorial footnotes to the text below.

Five speakers contributed to the discussion in the two following sessions: Paul Mittler, M. Grossmann and Josef Breuer on November 4; Dr Teleky and Heinrich Weiss on November 11. Mittler criticized the lack of a precise definition of hysteria. He argued that account must be taken of nonsexual as well as sexual factors in aetiology, and that both types of influence acted through the mediation of shock or similar affective states. Grossmann said that, while the concept of hysteria had gained in clarity, its differential diagnosis remained difficult and uncertain. He illustrated this point by describing hysterical disturbances of the laryngeal function.

Breuer, speaking as an older man, already distinguished and respected, gave Freud his support. Even if he had himself laid the foundation stone, he stressed that the

building – the theory of repression and the influence of unpleasure on repression – was Freud's intellectual property. While he admitted to doubts and reservations initially, he said that he had now been fully convinced by the work, and felt that he was in a position to reassure those who still doubted. Freud's theories were not simple *a priori* constructions but the necessary conclusions drawn from his clinical observations. Anyone who had experience of hysterics would realize that they were very difficult to influence, and it was not plausible to say that Freud had forced them to acknowledge fictitious memories. He defended Freud against the charge of attributing a sexual origin to every hysterical symptom; it was rather the condition of hysteria itself which he claimed had a root in sexuality. Such ideas would have been accepted without demur if applied to young men. It was part of Freud's achievement that he had embarked on an understanding of sexuality in women. Some of the interpretations now given might be strained, but Breuer reminded the audience that the detailed conclusions were still provisional.

Teleky congratulated Breuer and Freud on attempting to find a psychological explanation for the psychopathologies and hence open up the way for psychological treatment. He added that not all doctors would be as successful as Freud in using his treatment methods, and he would have liked these methods to be described in greater detail. The emphasis on sexuality in hysteria might be overdone, but was certainly justified in some cases. The name 'hysteria' showed that a sexual origin had been recognized from the time of antiquity. The value of physical methods of treatment in some cases ought not to be disregarded. Cures had been produced by ovariectomy or even, in one case, by a pretence that the operation had been carried out.

H. Weiss thought that Freud underestimated the effect of the 'struggle for existence' in modern civilized life, which he believed was most clearly evident in America. Hysteria resulted from a labile nervous system, and there did not need to be a sexual cause. It could develop from any psychical shock. One could not escape the impression that Freud's case histories were presented in such a way as to emphasize sexual factors and neglect other equally important causes. Despite his objections, he did not stand in complete opposition to Freud. He did caution, however, against indiscriminate use of Freud's type of anamnesis which, in less sensitive hands than Freud's own, might prove damaging to patients.

The two reports of the discussion (on which the above summary is based), like those of the lecture, are complementary. Breuer's contribution is given prominence in both. In a letter to Fliess, written on November 8, 1895, and continued on November 10, Freud remarked that Breuer's public defence of him did not accord with his attitude in private: 'Not long ago Breuer made a big speech to the physicians' society about me, putting himself forward as a convert to belief in sexual aetiology. When I thanked him privately for this he spoilt my pleasure by saying: "But all the same I *don't* believe it!" Can you make head or tail of that? I cannot' (Freud, 1950*a*, Letter 35).

Some further comment upon this apparently inconsistent behaviour of Breuer's, and upon the differences that led to the end of the scientific collaboration between the two authors, can be found above in the Editors' Introduction to the *Studies on Hysteria* (1895*d*) on p. xxi ff. and, in particular, p. xxiv f.

TWO CONTEMPORARY REPORTS OF A THREE-PART LECTURE 'ON HYSTERIA'

I. REPORT IN THE *WIENER KLINISCHE RUNDSCHAU*

Vienna College of Physicians

Session on October 14, 1895

We have not hitherto succeeded in accurately determining the scope and substance of the concept of hysteria. Whereas ten years ago the efforts of authors were still directed at detaching hysteria from the organic diseases, today it is our task to learn to distinguish it from the neuroses, particularly from neurasthenia. This increases the difficulties confronting the study of hysteria, because the neurasthenia concept is far more vague than is that of the other neuroses. Hysterical and neurasthenic elements very frequently co-occur, so that numerous authors consider a sharp differentiation to be impossible and say that hysteria and neurasthenia merge with one another.
